WITH SUPPLEMENT (Gratis) INDEX TO VOL. LXIV.

THE ELECTRICIAN:

THE OLDEST WEEKLY JOURNAL OF ELECTRICAL ENGINEERING, INDUSTRY, SCIENCE & FINANCE.

No. 1,666. [VOL. LXV.] FRIDAY, APRIL 15, 1910.

Registered at the General Post Office. ADDRESS: 1, 2 & 3, SALISBURY COURT, FLEET STREET, LONDON, ENGLAND.

SINGLE COPY SIXPENCE; BY POST 6½d. Abroad 9d. or $0.18c., or 90c., or 80pf. Ann. Sub. (U.K.) 26s Abroad 30s.

MAY 11 1910

BRITISH INSULATED & HELSBY CABLES,

ELECTRICAL CABLE MAKERS AND ENGINEERS, Ltd.

Works: PRESCOT, HELSBY, and LIVERPOOL.
Head Office: PRESCOT, LANCASHIRE.

BRANCH OFFICES:
LONDON, MANCHESTER, GLASGOW, BIRMINGHAM, CARDIFF, NEWCASTLE, DUBLIN, & BELFAST.

REGISTERED TRADE MARK.

JOHNSON AND PHILLIPS LTD
VICTORIA WORKS
CHARLTON. S.O. KENT
ESTABLISHED 1875.

CABLES.
SWITCHBOARDS.
SEARCHLIGHTS.

V. I. R. Cables and Wires.
Paper Insulated Lead Covered Cables.
Vulcanised Bitumen Cables.
Transmission Lines.

E. H. T., H. T., & L. T. Switchgear. H. T. Oil Switches, automatic or non-automatic, for Switchboard, or separate Mounting, and are designed for Direct Operation or Mechanical or Electrical Remote Control.

For NAVAL, MILITARY, and MERCANTILE PURPOSES.

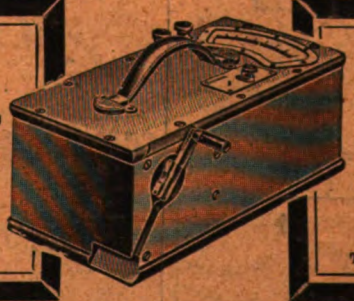
LIBRARY OF THE UNIVERSITY OF CALIFORNIA

FELTEN & GUILLEAUME-LAHMEYERWERKE A.-G.
CARLSWERK, MULHEIM-ON-RHINE.

ELECTRIC CABLES.

Agents for the United Kingdom
For Insulated Wires and Cables for Electric Light and Transmission of Power, and for Rail Bonds } The LAHMEYER ELECTRICAL CO., Ltd., 109-111, New Oxford St., London, W.C.
For all other Manufactures .. .. W. F. DENNIS & CO., 49, Queen Victoria Street, London, E.C.

N.C.S. INSULATION TESTING SET,
THE
"OHMER"
Combined Ohmmeter & Generator.



The LIGHTEST
The CHEAPEST and
The BEST.
PROMPT DELIVERY FROM STOCK.
NALDER BROS. & THOMPSON, LTD.,
34, Queen St., London, E.C.
Telegrams: OCCLUDE LONDON. Telephone: 123 & 124 Bank.

HENLEY'S PATENT
CABLE SUSPENDER

SAMPLE AND FULL PARTICULARS ON APPLICATION TO
W. T. HENLEY'S TELEGRAPH WORKS COMPANY, LTD.

NOTES.

Electromagnetic Physiological Effects.

FROM the earliest days of voltaic electricity the stimulation of nerve and muscle by electric currents has been familiar to the physicist, and within the last 20 years the application of this property has been extended to a marked degree in medical treatment and physiological research. So far, however, no corresponding magnetic effects have been discovered. This is not for want of investigation. Many years ago Lord LINDSAY (now the EARL OF CRAWFORD), assisted by Mr. CROMWELL F. VARLEY, constructed an enormous electromagnet, between the poles of which any observer might place his head; but the results were negative. Recently Prof. SILVANUS THOMPSON has turned his attention to the subject and has constructed a solenoid sufficiently large to admit an observer's head, the winding being traversed by an alternating current. This current is sufficient to produce a virtual field of about 1,000 C.G.S. units at the centre of the coil, or a maximum instantaneous value of 1,400 C.G.S. units. As will be seen elsewhere, on inserting the head into the interior of the coil there is a marked effect, a faint flickering illumination being perceived over the whole region of vision.

THROUGH the courtesy of Prof. THOMPSON we have had an opportunity of experiencing this new phenomenon. There is no question that a very distinct result is produced by the alternating field, though in all probability the effect will vary somewhat, depending on the subject. This is only to be expected with such an organism as the eye, which varies enormously in individuals and is often somewhat abnormal. The sensation we experienced was chiefly one of mechanical twitching of the eyelids when these were closed; there was also a sense of flicker, or rather the discomfort of flicker, though very little illumination was noticeable. In some eyes there might very possibly be more illumination and less twitching, and in any case the full effect on the eye, as in most experiments on vision, is liable to be missed unless the observations are fairly prolonged. It is somewhat curious that a current with a frequency of 50 periods per second should give rise to flicker effects which appear to have a frequency of, say, one-tenth this number, or less. As to the prime cause of the phenomena, it will, no doubt, be agreed that the effect is due to induced currents rather than to any magnetic effect pure and simple. The magnetic properties of the constituent parts of the eye, including nerves, are feeble, but their sensitiveness to currents is well known, though it must be remembered that in speaking of currents in such cases we imply the use of electrodes. In the present instance we are dealing with electrode-less currents. Possibly, such currents may find a useful application in electromedical work, but whether this be so or not Prof. THOMPSON'S observations open up an interesting field for investigation, and we do not doubt that the subject will be taken up with eagerness.

Allocation of Profits.

A DECISION of considerable importance to local authorities was given on Tuesday last by a Select Committee of the House of Commons. The point arose in connection with a clause in the Glasgow Gas Consolidation Bill, whereby the Glasgow Corporation sought powers to apply moneys out of the profits of the gas undertaking to the relief of rates. As proof that they did not intend to make undue use of this power, it was mentioned that during the last 40 years the Corporation had so applied

Digitized by Google

only £21,000; but, nevertheless, the Select Committee struck out the clause, being probably influenced by the contention of the other boroughs and districts within the area of the gas supply that any profits should be applied to the reduction of the price of gas. This decision, of course, only applies to Glasgow, and, moreover, only to the gas undertaking in that city, but it probably marks the advent of a new feature in municipal finance.

It has been the custom in some cases for large contributions to be made from the profits of municipal tramway and electricity undertakings to the relief of rates. As an instance of this, we may mention that a sum of over £320,000 has been paid by the Manchester Corporation Tramways department to the City Fund during the last six years, whilst a similar sum has been contributed by the Glasgow Corporation Tramways in the last 15 years. Compared with these amounts, the use made of the profits of the Glasgow Gas department for the relief of rates is but trifling, so that the action of the Select Committee is the more noteworthy. It is true that the ruling of the Committee is an isolated case, but it is not unlikely that similar restrictions will be placed in the future on the use made of the profits of other municipal undertakings. In that case, ardent advocates of municipalisation will no longer be able to appeal to the public on the ground that municipally controlled undertakings provide large funds for relieving the rates. From a logical point of view little can be said in support of the policy of utilising the profits of any particular municipal undertaking for the benefit of all sections of the community, so that we think the action of the Select Committee will be to the benefit of municipal enterprise generally.

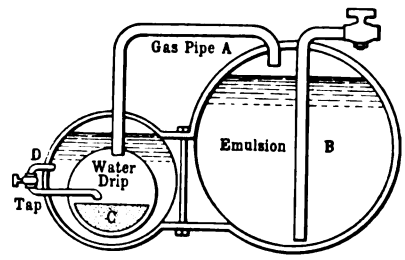
Comparisons.

There is an old and not untrue saying that "comparisons are odious." Nevertheless—particularly in technical matters—comparisons are often necessary, and many of the Papers that are written for our institutions deal very largely with the qualities of one kind of apparatus as compared with another. In some cases the comparisons are made in such a way that the reader is left in complete ignorance of the particular device to which allusion is made, and although this method fails to give the most complete information, it is sometimes adopted of necessity. The reader must then guess, as best he can, the identity of the inferior or superior article. In other cases the names are plainly stated, and this, no doubt, is preferable from the reader's point of view. We think that authors should in any case make up their minds quite definitely which course they mean to adopt. In an otherwise excellent paper by Mr. A. Gerrard, read before the Institution of Electrical Engineers at the last meeting, comparisons were made between the Westinghouse track brake and another track brake, of which the name was not given. In the case of the Westinghouse brake the name was plainly stated, and as a drawing was given of the brake with which it was compared, anyone familiar with the subject could recognise the latter. Other readers, however, would be in ignorance, and this brought forth a reasonable protest from Mr. A. W. Maley, the inventor of the anonymous specimen, and led to some personalities which could only be regarded as a "regrettable incident" in an otherwise interesting discussion. Mr. Gerrard's plain statement, that he had omitted the name because he did not wish to include it, does not seem to us to be a very satisfactory conclusion of the affair. At least, we hope that other authors will take warning and not put themselves in the wrong by including names in certain cases and omitting them in others, a course which is on neither side of the hedge.

Personal.—The King has granted to Mr. William Bullard, manager of the Eastern Extension Telegraph Co. at Shanghai, His Majesty's Royal licence and authority to wear the Insignia of the Third Class of the First Division of the Imperial Order of the Double Dragon conferred upon him by the Emperor of China in recognition of valuable services rendered.

Electrolytic Disinfecting Fluid.—In Poplar, for over four years, a plant has been at work making electrolytic disinfecting fluid for disinfecting purposes, and last year the Council resolved to have another plant installed. This plant is now in working order with all improvements, the outcome of over four years' work. The two plants work absolutely automatically by the aid of electricity, turning out within eight hours 400 gallons of the fluid with over 5 grammes of chlorine per litre.

A Gas-Pressure Sprayer Worked with Acetylene.—At a recent meeting of the Faraday Society Mr. E. Kilburn Scott gave an account of a gas sprayer which has come largely into use in Australia, the pressure being obtained by the action of water upon acetylene. The construction of the apparatus is sufficiently indicated by the adjoining illustration. It is



Gas-pressure Sprayer.

used for horticultural work, whitewashing buildings, distempering rooms, spraying sheep instead of dipping, suffocating rabbits, and many other purposes. The saving in labour is found to be very large, and the effect on the consumption of calcium carbide has been quite marked. Five years ago the consumption was just over 2,000 tons per annum, but in four years the consumption rose to over 8,000 tons, and the price at Sydney fell from about £18 to £10.

Toronto Railway System and Electrolysis.—An interesting report on this subject has lately been issued and is summarised in the "Canadian Electrical News." The report classifies the various methods of protection against electrolysis under three heads: (1) The conduit system for return wires, as used in New York and Washington, &c., and now being installed in certain sections in Winnipeg; (2) the double overhead trolley system as operated in Cincinnati and on various suburban lines in the District of Columbia, and (3) the modern bonding system, as used by the Toronto Railway Co. Mr. Strickland is of opinion that the latter system, very carefully installed, is the equal of either of the others. The bonds are in very good order, and the loss of pressure in the track circuit is only ½ volt to every 500 ft.

Cable Interruptions.	Date of Interruption.

Royal Society.—Among the Papers read at the meeting of this Society yesterday afternoon was : "A Physiological Effect of an Alternating Magnetic Field," by Prof. S. P. Thompson, F.R.S. An abstract of this Paper will be found in another column of this issue.

Transmitting Observations on Halley's Comet.—The Spanish Telegraph Administration, acting on instructions of the Government, has made arrangements, in view of the coming observations to be carried out by an International Commission at Teneriffe, to construct a telegraph line from Orotava to the base of the Teide mountain (Peak of Teneriffe), and communication will be completed from this point to the spot selected for the observations by a land cable up the slope of the mountain.

The Effect of Electricity on Plant Growth.—Some interesting observations on this subject are given in the "Journal" of the Bath and West and Southern Counties Society. It is held that such fruits as strawberries are most suitable for treatment, since there seems to be some fear of "over-stimulation" in the case of fruit trees, and wheat is said to be less responsive, while legumes are adversely affected. Actual increases of production recorded are 39 per cent. in wheat, 65 per cent. in roots, and 80 per cent. in strawberries.

Engineering Standards Committee. — Mr. Leslie S. Robertson, the secretary of the Engineering Standards committee, states that the Government have intimated their willingness to contribute £500 per annum for three years to the committee. The Secretary of State for India in Council has also made a grant to the committee of £300 towards the expenses incurred in the preparation of the Third Report on Standard Locomotives for Indian Railways, a work which was undertaken at the request of the Indian Government.

The New Buenos Ayres-Ascension Cable.—Much interest is being taken in Argentina in the operations connected with the laying of the new cable from Ascension Island to Buenos Ayres. The land-line work is considerable and is being carried out by W. T. Henley's Telegraph Works Co. Two lines are being provided, one placed overhead and the other laid underground in iron pipes, representing a length of about 50 miles in all. It is anticipated that the first message will be sent over the new cable on or about May 25th.

Thermic Effects of Undamped Electric Oscillations on the Human Body.—In a recent issue of the "Elektrotechnische Zeitschrift" the thermo-penetration of oscillations was studied by Prof. von Klingmüller and Mr. F. Bering. The heating is a maximum in the neighbourhood of the electrodes, especially on the skin, and becomes more rapid as the electrodes are brought closer together. When the electrodes are some distance apart the heating effect cannot be noticed to any great depth even when it is quite unbearable near the electrodes. The temperature does not become normal for some considerable time after the electrodes have been removed.

Nitric Acid from the Air.—The "Engineering and Metallurgical Review" states that Mr. F. I. Dupont, who has paid considerable attention to the production of nitric acid by electric discharges through air, has been granted another patent for a furnace for this purpose. The air is passed through a silica tube containing the electrodes between which the arc is formed. The silica tube is surrounded by a glass tube through which a cooling liquid is passed. The field magnets are energised by a polyphase current, thus producing a rotary magnetic field which causes the arc to rotate around the inner surface of the silica tube. Air is forced through the passage into the zone between the electrodes; it is heated by the rotary arc, but as soon as the rotating arc passes from any portion of the air, this air is immediately subjected to the cooling action of the walls, and its temperature is so rapidly reduced as to prevent the formed nitrogen oxide from being again largely decomposed.

Regulation of Wireless Telegraphy.—According to a proposal which has been approved by the Navy Department and the Department of Commerce and Labour in the United States, and has been submitted to the House of Representatives, wireless telegraph stations must be licensed and the operation of an unlicensed station will be made a misdemeanour, for which a fine of £100 can be imposed. The President may, in time of war or public peril, order any station to be closed. Interference with messages, which has been the source of much trouble, is placed under a penalty of £100. The fee for first-class licences, which are those for land stations, will be £20, and that for the second class, those on ships, is to be £1. Messages relating to ships in distress are to have priority. Fraudulent messages are forbidden, and a fraudulent distress signal may be punished by a fine of £500 and imprisonment for five years. The House Merchant Marine Committee has determined to report favourably upon a bill requiring the equipping of ocean-going steamers with wireless telegraphic apparatus.

Obituary.—W. L. Harvey.—We regret to record the death of Mr. W. L. Harvey, Secretary of the Government of India for Commerce and Industry, which occurred at sea between Aden and Suez. At Calcutta, Mr. Harvey was responsible in the Executive Council for the railway, postal, telegraphic and other revenue-earning departments, as well as for the promotion of the general, industrial and commercial development of the country. The outstanding feature of his tenure was the reform of the telegraphic service and reconstitution of the department under the expert advice of Mr. J. Newlands, whose services were lent by the Postmaster-General. The strike of the traffic staff in consequence of the new arrangements was firmly and tactfully handled by Mr. Harvey, and though at first the commercial community took alarm, he was able eventually to secure its general support.

Sir Walter Scott.—We also regret to record the death of Sir Walter Scott, who was best known to electrical engineers for his connection with the building of the Tube railways of London.

James Tomkinson, M.P.—We also regret to announce the death of Mr. James Tomkinson, M.P., Chairman of the North Wales Power & Traction Co. Mr. Tomkinson took part in the House of Commons steeplechase on Saturday; his horse stumbled, deceased was thrown and received injuries to which he succumbed.

Electrically Controlled Ventilation for Mines.—"Le Génie Civil" describes an electrically controlled fan which has recently been set to work at Rheinelbe. It supplies the mines with 200,000 cubic ft. of air per minute under a water pressure of 470 mm. when running at 363 revs. per min. The 1,000 H.P. motor used is connected to the mine network, the voltage being 5,000 volts and the frequency 50, through a regulating transformer consisting of a 200 kw. three-phase motor and an 85 kw. asynchronous generator. This latter motor is connected in cascade with the fan motor rotor whose slip energy it absorbs and, being in turn connected to the asynchronous generator, returns this energy to the line. A regulator is provided by means of which the motor-generator group can be run at any speed. The generator is then connected to the network and its speed raised by gradually short-circuiting the regulator. The fan motor is then started up, and when it has reached full speed its slip rings are automatically connected to the transformer group. The speed is regulated by altering the excitation of the motor in the transforming set, 20 speeds being possible between 268 and 363 revs. per min. For each position of the regulator the speed is constant, whatever the load.

New Accumulator Car for the Prussian State Railways.—According to the "Elektrotechnische Zeitschrift," the new accumulator car which has recently been set to work on the Prussian State Railways differs somewhat in its construction from that described in The Electrician, Vol. LXII., p. 419. The principal alteration consists in the adoption of two further axles, the new car possessing six. It was found that with four axles the axle-pressure was too great, while with six it does not exceed 6 tons per axle. The new axles are placed under the battery boxes at each end of the double car and all six are free to move independently of the others. The second alteration is the obligatory provision of electric, in addition to compressed air, braking, though some

Digitized by Google

of the older cars were also so fitted. In the course of tests, on one of these latter, it was found that the car when running at 35 miles per hour could be brought to a standstill in 230 yards with the air-brake, and in 115 yards with the electric brake. This result led to the compulsory provision of the electric brake. The third modification is the attachment to the arrangement, whereby the controller handle was brought to the "off" position and the brake applied if the driver released his hold, of a time-limit device whereby the action is delayed for several seconds. In this way, accidentally releasing the handle does not bring the car to rest, while safety to the passengers in case the driver is taken ill is still ensured.

Electricity in the Manufacture of Iron and Steel.—"Stahl und Eisen" has compiled a list of the electric furnaces now at work smelting iron or steel. The list totals 114 furnaces for steel making, of which 77 are classed as arc furnace two generate their heat by a combination of arc and resistanes and 35 are induction furnaces. Seven of the steel furnaces are at work in England and a number in America, but the great majority are on the Continent, principally in France and Germany. Most of the furnaces are of small capacity, generally between one and five tons, and are engaged upon high-class steels, but a fair proportion are working on ordinary steels such as structural steels, steel castings and railway material.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. W. C. Clinton contributes an article on "The Determination of the Efficiency of Continuous-Current Machines."

We give an account of the discussion which followed the reading of Mr. A. Gerrard's Paper on "The Progress of Electric Braking on the Glasgow Corporation Tramways," before the Institution of Electrical Engineers.

At the recent meeting of the Association of Teachers in Technical Institutions (Yorkshire Branch) Dr. R. Pohl read a Paper on "The Movement Towards a National System of Technical Education."

We give an account of the discussion on the Paper by Dr. R. Pohl, read recently before the Yorkshire section of the Institution of Electrical Engineers on the subject of "The Testing of Intermittent Motors."

A lengthy Board of Trade enquiry was held at Radcliffe last week into the application of the Lancashire Electric Power Co., for a Provisional Order, to enable them to supply electricity in the municipal area in competition with the Council. In the course of the enquiry it was intimated on the part of the company that they only required an order to enable them to supply power to consumers who required over 30 H.P.

The Wolverhampton Corporation decided on Monday to apply for sanction to a further loan of £23,000 for extensions to the Electricity Undertaking.

On Monday the Manchester Corporation adopted a recommendation of the Electricity committee to borrow £40,000 for the Electricity department.

An inquiry was held on Tuesday into the application of Gillingham Council for permission to borrow £3,000 for electric generating plant.

Parliamentary.—A Select Committee of the House of Lords approved the tramway clauses of the Handsworth District Council's Bill.

The Metropolitan District Railway Bill (to provide increased railway facilities from Hammersmith to Turnham Green) was passed by a House of Lords Committee on Monday.

Directors' Reports.—The report of the directors of the Metropolitan Electric Tramways gives particulars of the progress made during the past year, and states that four additional sections of light railway were opened in Middlesex during the year, bringing the total length of the system to 51½ miles, and that 4¼ miles are under construction. The traffic receipts show a considerable increase.

The directors' report of the North Metropolitan Electric Power Supply Co. gives particulars of the progress made during the past year. The units sold were 16,402,447, an increase of 2,332,836, or 16·5 per cent. The business of the North Metropolitan Electrical Power Distribution Co. (at Barnet, Enfield, Hertford and St. Albans) is also stated to be expanding satisfactorily.

At the meeting of the South Wales Electrical Power Distribution Co., on Tuesday, the chairman gave particulars of the progress made by the Treforest Electrical Consumers Co. The South Wales Co. was now making a trading profit. Some new collieries had made arrangements to take electrical energy, and the installations of some of the old collieries had been extended.

Messrs. Babcock & Wilcox have increased their dividend from 20 per cent. for 1908 to 24 per cent. for 1909.

INSTITUTIONS AND SOCIETIES.

BRITISH ASSOCIATION.—A preliminary programme of the annual meeting of this Association, which begins at Sheffield on August 31st next, has now been issued. The president (the Rev. T. G. Bonney) will have the assistance of a strong body of representatives of the municipal, educational, ecclesiastical and commercial interests of the city, who have been appointed as vice-presidents for the meeting, headed by the Lord Mayor, Lord Fitzwilliam. To the list of sections already announced there has been added, as in previous years, a sub-section of Agriculture, which this year will be formed under the section of Chemistry, with Mr. A. D. Hall, F.R.S., as chairman. The conference of delegates of corresponding societies will assemble this year, as usual, at Sheffield during the meeting, and not in London, as last year, when the meeting was in Canada. Its chairman will be Dr. Tempest Anderson. The reception-room and administrative offices during the meeting will be established in the Cutlers' Hall. It is centrally situated, and most of the sectional meeting rooms will be within a very short distance of it. The opening meeting will be held in the Victoria Hall on Wednesday evening, August 31st, when Prof. Bonney will deliver his inaugural address. In the same hall the first evening discourse will be delivered on Friday evening, September 2nd, by Prof. William Stirling, on "Types of Animal Movement," and the second on Monday evening, September 5th, by Mr. D. G. Hogarth, on "New Discoveries about the Hittites." The concluding meeting will be held on Wednesday, September 7th. Receptions will be given by the Lord Mayor and by the University, and a number of garden parties will be arranged. Arrangements have been made with the railway companies to issue return tickets at reduced fares to members attending the meeting.

ARRANGEMENTS FOR THE WEEK

FRIDAY, April 15th (to-day).

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street, Piccadilly, W. Discourse on "The Chemical Significance of Crystal Structure," by Prof. W. J. Pope, F.R.S.

TUESDAY, April 19th.

FARADAY SOCIETY.

3:30 p.m. Visit to the Electrolytic Depot of the Stepney Corporation, Violet-road, Bromley-by-Bow.

THURSDAY, April 21st.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at the Institution of Civil Engineers, Great George-street, Westminster, S.W. Paper on "Hydro-Electric Installations of Sweden," by Mr. A. V. Clayton.

FRIDAY, April 22nd.

PHYSICAL SOCIETY.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. Agenda: "Further Tests of Brittle Materials under Combined Stress," by Mr. W. A. Scoble, and "The Magnetic Balance of Curie and Cheneveau," by Messrs. C. Cheneveau and A. C. Jolley.

ROYAL INSTITUTION.

9 p.m. Meeting at Albemarle-street, Piccadilly, W. Discourse on "The Telegraphy of Photographs, Wireless and by Wire," by Mr. T. Thorne Baker.

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. B. Crompton, C.B.

The following orders have been issued for the current week:—

Saturday, April 16th, "A" and "B" Companies.—Parade at Headquarters 3:30 p.m., Drill Order.

Monday, April 18th, "A" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 9:30 p.m.

Tuesday, April 19th, "B" Company.—Infantry Drill, 7 to 8 p.m. Technical Drill, 8 to 10 p.m.

Wednesday, April 20th, Gymnasium.—6 to 9:30 p.m.

Thursday, April 21st, "C" Company.—Recruits' Infantry Drill, 6 to 6.45 p.m. Company Drill, 7 to 8 p.m. Technical Drill, 8 to 9:30 p.m.

Friday, April 22nd, "D" Company.—Recruits' Infantry Drill, 6:15 to 6:45 p.m. Company Drill, 7:30 to 8:30 p.m. Technical Drill, 8:30 to 9:30 p.m.

THE AUTOMATIC REGULATION OF ALTERNATORS*

BY M. SEIDNER.

Summary.—After discussing the object and possibilities of regulation, and outlining the general theory, the author passes on to discuss regulators of general interest, and more especially those types due to Alexanderson, Walker, Thury and Tirrill, which are of practical value.

In a previous article ("E.T.Z.," 1908, p. 450) the author has shown that the methods used for the inherent pressure regulation of alternating-current generators do not comply with modern requirements in either a technical or an economical sense. The inherent regulation of the alternator limits the pressure rise by means of saturation. In this way it is not possible to provide economically for a less rise of pressure than 16 per cent. from full load at $\cos\phi=0{\cdot}7$ to no load with constant speed and excitation. The difficulty to improve on this figure explains why it is accepted in practice. A lower pressure rise would, however, be very desirable, especially for mixed loads. But even the above value of 16 per cent. is only obtained by sacrificing efficiency and output. So long, however, as these deficiencies were only regarded as a feature of the installation as a whole they did not appear very serious, but increasing competition and the present-day practice of considering the several parts of the installation separately, has convinced manufacturers that radical changes must be made if the expensive means of inherent pressure regulation are to be replaced by other and cheaper methods. Another important factor in connection with this problem is the rapid advance of the turbo-alternator. In these machines, owing to the difficulty of carrying away the heat, high magnetic densities become undesirable, and a pressure rise of 25 to 35 per cent. is often allowed.

The first alternators were machines with a large pressure rise, so that the necessity for providing good regulation soon became apparent, and the idea to provide alternators with self and compound excitation, similar to the compound continuous-current dynamo, came quite naturally. This method was soon given up, however, for the means of calculation and workshop arrangements at that time were quite inadequate for such work. A closer study of the design of generators resulted in the adoption of inherent pressure regulation. Heyland was the first to show that alternators with external pressure regulation are much cheaper than normal generators with a low pressure rise. The former machines, with large self-induction, are also better for parallel working than the latter.

The Regulator.

A good method of regulation should possess the following characteristics:—

The *factor of safety of working* is certainly the most important. The factor of safety of a construction is greater the smaller number of movable parts. Consequently, in this respect, the best methods of regulation are those that require fewest machines and movable elements. Arrangements, therefore, which, in addition to the exciter, require separate machines and apparatus are disadvantageous.

The Speed of Regulation.—Regulation should take place so quickly that pressure changes are avoided. The pressure of an alternator depends on the equilibrium of the magnetising forces due to the alternating and continuous currents. If this equilibrium is disturbed a corresponding change of the field energy is necessary. The time taken for this change depends on the time-constant of the magnetic circuit. In the case of alternators with exciters, the field energy of both generator and exciter must change with the load. The flux in the exciter must be adjusted so that its terminal pressure corresponds to the load on the generator. The adjustment of this flux takes a certain time, consequently the change in the continuous-current excitation does not occur simultaneously with that in the alternating-current excitation, and a variation in the pressure of the alternator will ensue. The new pressure of the generator must now be adjusted, which is accompanied by a corresponding change in its field energy. The time taken to accomplish this increases rapidly with the inertia of the exciter. If the pressure of the exciter were to respond immediately there would be no change of pressure at the generator. This is the ideal case, which cannot, however, be attained in practice. For quick action, therefore, the ideal method would be to regulate by armature reaction without the aid of an exciter. The regulation is also very rapid with arrangements where no exciter is present, but the exciting current is part of the alternating current rectified.

In arrangements where exciters are used the speed of regulation depends on the rapidity with which the exciting current of the exciter can vary. When the exciter pressure is controlled by means of a shunt regulator, there are three ways in which the shunt resistance can be varied. Either the resistance is slowly switched in or out until it reaches its final value, or it is made to attain its final value in one step; or a greater resistance than that corresponding to the proper value is used, which is switched in or out as soon as the pressure reaches its normal value.

It is clear that the first method leads to the slowest regulation, whilst the last leads to the quickest. The same means are also applicable where, instead of the shunt resistance, the exciting current is varied by introducing a corresponding E.M.F.

Those methods where the regulator plays the part of a relay—that is, where the variation of the exciter pressure due to the regulator causes a further change of pressure—can only admit of a slower regulation than those where the exciting current is adjusted independently of the terminal pressure. Consequently, exciters excited with constant pressure are always more quickly excited than self-excited machines; compound exciters always excite more slowly than shunt machines, whilst differentially excited machines accelerate the excitation. Likewise, the permanent resistance in the shunt circuit always accelerates excitation. Methods where the current for regulation requires a current transformer assist quick regulation. The current transformer produces the secondary current corresponding to the rate of conversion, independently of the secondary resistance, and therefore independently also of the inductive resistance of the magnet windings (which latter retards the change of current and consequently the regulation).

Stability of Regulation.—The regulation following a disturbance is completed when the condition of equilibrium is restored and the pressure correctly adjusted. These two conditions should occur simultaneously. If this is not the case, the regulating mechanism will continue to operate further, and conditions may arise whereby hunting occurs.

This action does not occur in compounding methods, for here the exciting current is made to correspond to the load current independently of whether the resulting pressure is correct or not. Thus the question of stability has only to be reckoned with in mechanical regulators which act on an astatic principle and continue to operate until the correct pressure obtains.

Effective means of preventing this over-regulation are the retarded and step-by-step methods which are employed in most mechanical regulators. These devices, however, lead to slow-speed regulation, and are therefore unsuitable for alternators. Over-regulation can best be avoided—without sacrificing speed—by the use of a "back- or reverse-control," and the best regulators are now designed on this principle (see below).

Cost.—The regulator should be as cheap as possible to justify its replacing inherent regulation. If the arrangement can be adapted so that an overall economy in the outlay results, we have the further advantage of, say, a 5 per cent. regulation instead of an 18 per cent.

Parallel Working.—The regulation of machines running in parallel, or the automatic distribution of the wattless current between the various units, should be possible without regard to type and output. With regulators which are not actuated by pressure variations, but by current variations—that is, by compounding—this is possible. Each machine can be provided with a separate regulator or compounding device which adjusts the excitation of the machine in question, so that the wattless current is properly divided between the several machines.

The astatic pressure regulators, and more especially the modern quick-acting regulators, cannot work in parallel. Machines in parallel are provided with a single regulator. From this point of view, astatic regulators have two important disadvantages. Firstly, the magnitude of the energy controlled by a single regulator cannot be increased indefinitely, so that the regulation of large central stations and units becomes difficult; and, secondly, only machines of the same type and size can be governed in this way, since the apparatus cannot distribute the wattless currents between the several machines.

Overload.—The maintenance of a constant pressure on overloads and short-circuit is a source of danger, so that a good regulator should allow the pressure to fall when the current exceeds a certain value.

As regards *manufacture*, it is well to have a regulator that can be fixed to machines already in operation, or, in other words, no constructional alterations in the machines should be necessary. It is also desirable to have the regulation as *accurate* as possible, so that the limits of pressure variation are reduced to a minimum; further, the pressure variations due to changes in speed should not be too large.

The Pressure Rise.

We can now see how the exciting current must vary in order to obtain a constant pressure at the terminals. It is not necessary to follow this into close detail, for, as pointed out above, great accuracy in maintaining the pressure constant is not the chief object

* Abstract of an article in the "Elektrotechnische Zeitschrift."

Digitized by Google

of regulation; in addition to this, there are so many disturbing influences at work (heating of field coils, brushes, &c.) which make such exactness superfluous. For this reason the effects of leakage will also be neglected.

In Fig. 1, let OA represent the ampere-turns required on no-load. The induced pressure OB of the generator lags 90 deg. behind this. Let the machine be loaded with a current, i, lagging behind the pressure OB by the angle ϕ; then we can represent by OC the ampere-turns in the armature, which react on the main flux. In order to keep OB constant, the ampere-turns OA must be increased in magnitude and direction to AC.

When $\phi=0$, the point C lies on OB and moves along this line as the load varies. Hence, to compensate the pressure drop, an alternating current is required proportional to the load current of the generator, or, rather, to the ampere-turns of the armature. Further, the vector of the compensating M.M.F. must vary with the phase displacement. The resultant alternating-current ampere-turns CA are formed from the terminal pressure and the load current of the generator and converted into continuous current by some suitable means. Under normal conditions two transformers—namely, a current and a pressure transformer—are used to give CA. The two transformers which produce the components CO and OA cannot merely be connected together. If, for example, they are joined in parallel, the secondary pressure is already fixed by the potential transformer, and cannot be altered by the current transformer (assuming the latter of normal construction). On the other hand, when connected in series, the current transformer determines the magnitude of the secondary current, and this cannot be altered by the pressure transformer. The continuous current for excitation would, therefore, be regulated either by the pressure transformer alone or by the current transformer alone.

The remedy suggests itself. With transformers in parallel, the pressure transformer must have the property of neutralising the secondary current produced by the current transformer by means of a primary winding of equal magnitude but opposite direction. This is accomplished by inserting in series an inductive or ohmic resistance with the primary or secondary winding of the potential transformer, whereby the latter assumes more or less the properties of a current transformer. With the transformers in series, on the other hand, the primary or secondary winding of the current transformer must be placed in parallel with a corresponding resistance, which gives this transformer more or less the characteristics of a pressure transformer. The same result can be obtained by including these resistances in the transformers themselves. Thus, with the parallel connection, the pressure transformer is given a large leakage, whilst with the series connection the current transformer is made to take a large magnetising current.

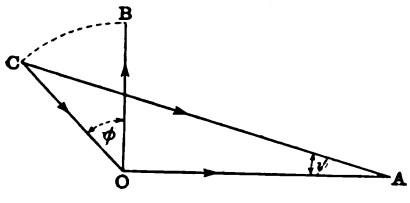

Fig. 1.—Diagram for Regulation.

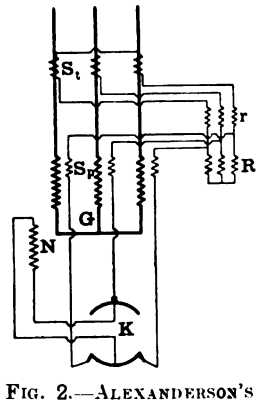

Fig. 2.—Alexanderson's Arrangement.

Classification of the Methods of Pressure Regulation.

Several different methods are described and criticised in the last section. Although there are many arrangements for compounding asynchronous generators, only methods for regulating synchronous machines will be discussed, as the former type has not yet become of great practical importance. The several methods may be classified into the following six groups:—

Group I.—In this group are classed all methods where the exciting current necessary to neutralise the pressure changes due to the varying current or load is produced in such a way that the corresponding alternating current is converted into continuous current by means of a commutator rotating synchronously with the generator. To this class belong the methods used by Ganz, General Electric Co. and Corsepius. These methods have recently been greatly improved by Heyland and Alexanderson.

Group II.—In this group the current required to compensate the pressure variations is also converted from alternating into continuous, but here a special field is produced to assist commutation. This group can be split up into two classes. The former includes those methods where the no-load current is also taken from the alternator; these are the converter methods. In the second class the exciting current on no load is supplied from an exciter. Here we have the arrangements of Hutin, Leblanc, Boucherot, Blondel, Rice, Danielson, Steinmetz, Ziehl, Roth, Union, &c.

Group III.—This includes all arrangements where the alternating current required for regulation is obtained electrolytically or thermally by means of stationary apparatus. Such a method is that due to Dobrowolsky.

Group IV.—The magnetic reactance of the armature is used for regulation. Examples, Walker and Heyland.

Group V. includes the arrangements where the alternating current is not converted into continuous, but the former actuates a resistance by mechanical means and inserts the same in the exciter field circuit. Here may be mentioned the regulators of Blatly, Thury, Dick, Thieme, Tirrill, Schwaiger and the various contact voltmeter methods.

Group VI.—Here, as in the last group, a rheostat is operated not mechanically, but purely electrically, magnetically or thermally, as illustrated by the methods due to the author, Crompton & Co. and Parsons.

With the exception of Group V., all methods have some similarity to the compounding of continuous-current machines, and have been referred to as such in the literature on the subject.

(To be concluded.)

EFFECT OF TEMPERATURE UPON THE MAGNETIC PROPERTIES OF ELECTROLYTIC IRON.*

BY E. M. TERRY.

Summary.—The author describes investigations of the magnetic constants of pure electrolytic iron at various temperatures, to determine to what extent the phenomena already observed are characteristic of the iron itself. The principal characteristics of Burgess electrolytic iron established by this investigation are: Freshly prepared iron is very hard magnetically. Different samples show marked dissimilarities at low fields, which differences disappear upon annealing at 1,000°C. For large fields, all samples are quite similar. Plunging into liquid air produces no permanent hardening. The retentivity has a maximum in the neighbourhood of room temperature. Marked softening magnetically occurs at the hydrogen transformation points. Ferromagnetism reappears on cooling at the same temperature at which it disappears on heating. This temperature is 785°C. The depression in the permeability temperature curves obtained by Morris does not exist for this iron. The best temperature for annealing is 1,100°C. Although when properly annealed it has a lower coercive force and a higher maximum permeability than Swedish iron, its high retentivity causes a large hysteresis loss.

Although much study has been devoted to the magnetic properties of iron as a function of temperature, in most cases the purity of the iron has been considered only in a general way. Since the magnetic properties of iron depend to so great an extent upon the presence of certain impurities, notably carbon, silicon and manganese, and in Burgess electrolytic iron we have an iron of extraordinary purity, it seemed worth while to repeat and extend some of the earlier experiments with a view to determining to what extent the observed phenomena are characteristic of iron itself, and to correlate them with metallurgical changes. The author first gives a brief summary of previous work.

In 1900, Wills studied the effect of temperature on the field which gives the maximum permeability. Working with wrought iron and alloys of aluminium, nickel and manganese he found that the maximum permeability occurs at lower fields as the temperature is raised, the relation being nearly linear. After his work the question of the effects of temperature on the magnetic properties of iron seems to have been regarded as settled, attention having been turned for the most part towards alloys. However, the recent perfection, by Prof. C. F. Burgess,† of the University of Wisconsin, of an electrolytic process for the production of very pure iron in large quantities has afforded an opportunity to study further the magnetic properties of this element.

Electrolytic Iron.—Owing to the difficulties of production, electrolytic iron has hitherto been very little studied magnetically, the work having been confined to room temperatures. The author, therefore, investigated the magnetic constants of this pure iron at various temperatures, ranging from that of liquid air to the temperature of magnetic transformation, with a view to determining, as far as possible, to what extent the phenomena already observed

* Abstract of an article in the "Physical Review."

† "Iron and Steel Mag.," Vol. VIII., p. 48, 1904.

Digitized by Google

are characteristic of iron itself, and to point out the effects of impurities.

The iron used was twice deposited from an electrolyte consisting of ferrous and ammonium sulphates, the current density being about 6 amperes per square foot, and requiring about four weeks to produce a plate 1 in. thick. Plates have been made weighing 75 lb. Chemical analyses have shown that this iron is very pure. In fact, the impurities are so slight that special methods have had to be devised to determine them. The average of several analyses is given below and may be taken as a fair indication of the purity.

Sulphur.	Silicon.	Phosphorus.	Manganese.	Carbon.	Hydrogen.
0·001 %	0·003 %	0·004 %	None	0·012 %	0·072 %

It will be noted that the amount of hydrogen present greatly exceeds that of all the other impurities combined, and it is to the presence of this element that the characteristic properties of electrolytic iron are usually ascribed. Burgess and Taylor* made a preliminary study of single refined iron about two years ago, and found that it is both magnetically and mechanically very hard. During the past year Burgess and Aston have been making an extensive study of the magnetic properties of alloys of this iron, but their results have not been published.

Of the various methods that have been used for magnetic testing, the Rowland ring seemed best suited for the present work. Since it gives a continuous magnetic circuit without a joint of any kind, no correction for demagnetising effect is necessary, and with a fairly uniform winding of the magnetising coil, it may be safely assumed that the flux crossing each section of the ring is the same, and that the leakage is negligible. If a D'Arsonval galvanometer is used, this method is independent of the earth's field or any other extraneous effects. It is, however, subject to three sources of error: (1) The field is not uniform across the specimen, and further, the mean field is not the field at the centre of the section calculated from the ampere turns. (2) Since permeability is a function of field strength, the mean flux density, calculated from the deflections of the galvanometer, is not the flux density at the centre of the section. (3) As pointed out by Ewing and Lord Rayleigh, for small fields and fields for which the differential permeability dB/dH is large, iron changes its magnetic state slowly, sometimes requiring several seconds or even minutes. Since the ballistic method requires that the total change shall take place before the galvanometer swings appreciably from its zero position, a serious error is introduced in testing iron possessing magnetic viscosity.

The first two errors may be reduced to negligible magnitudes by choosing the width of the ring small in comparsion to its diameter. Lloyd† has shown, for a ring with rectangular cross-section, that $\frac{H_0}{H_R} = \frac{1}{2p} \log \frac{1+p}{1-p}$, where H_0 = average value of field, H_R = field at mean radius of ring, p = ratio of radial width to mean diameter of ring. The value of "p" for the rings which I have used in this work was approximately 0·084. Substituting this value in the above formula we find $H_0/H_R = 1{\cdot}0024$.

The calculation of the error mentioned under (2) is very complex and has never been handled mathematically. Taking, however, a formula given by Richter,‡ we find values 1·0024 and 1·0021 in unannealed and annealed specimens respectively for W_0/W, where W_0 = hysteresis loss for uniform flux density, and W = hysteresis loss for actual flux density.

The effects of magnetic viscosity are nearly eliminated by a method suggested by Taylor.§ The essential feature of this modification is that all observations are referred to one of the retentivity points of the curve. For instance, to locate the point representing positive saturation, subject the specimen to maximum field: then close the secondary circuit through the galvanometer, and break the primary. The deflection of the galvanometer measures the difference of induction between the saturation and retentivity points. Points on the curve between these two are obtained in a similar manner, the iron having been first carried to saturation and the induction reduced to the desired value without breaking the magnetising current. For points between retentivity and negative saturation, the iron is first taken to positive saturation as before, and at once returned to retentivity by breaking the primary current. The secondary is then closed and the deflection taken when the proper magnetising current has been applied in the opposite direction. The calculation of the induction in terms of the field, as is ordinarily given, is then merely a matter of changing the origin by the amount of the retentivity, for computing which the necessary data are at hand. The advantages of this method are: (1) Observations on any one point may be repeated as many times as desired. (2) The magnetising current need be applied for only a few seconds, thus reducing its heating effect. (3) The errors due to magnetic viscosity, while not entirely eliminated, cease to be cumulative, as in Rowland's original method, and are reduced to negligible quantities. The work may be divided into three parts: To test the iron magnetically at different temperatures; to find the best temperature for annealing; to investigate the relation between crystalline structure and magnetic properties. The procedure in the first part was to run hysteresis and magnetisation curves at various intervals from the temperature of liquid air up to that at which iron ceases to be ferro-magnetic. For the lowest temperatures, the rings, after being wound, were dipped for an instant in melted paraffin then plunged into liquid air, and tested when the temperature had become uniform. To obtain temperatures intermediate between those of liquid air and the room, the following method, which is due to Knipp,* was used. A hollow copper sphere, with walls about 0·8 cm. in thickness, was mounted inside a cylindrical Dewar flask. To the lower side of the sphere was attached a copper spindle which dipped into liquid air. The Dewar flask was placed upon a platform which could be raised or lowered with a slow motion, while the sphere remained fixed. By properly adjusting the depth of the spindle in the liquid air, any desired temperature could be very constantly maintained. While there was an appreciable temperature gradient from top to bottom of the enclosure, the fall of temperature across the ring, which was placed horizontally, never exceeded 2 deg. For the production of high temperatures, an electric furnace of the Heræus type was used. For the measurement of temperature, two thermo-elements, whose E.M.F.s were determined by means of a specially constructed low resistance potentiometer, and an optical pyrometer were used.

Making the rings proved to be a matter of some difficulty, since freshly deposited iron is so hard and brittle that it cannot be cut

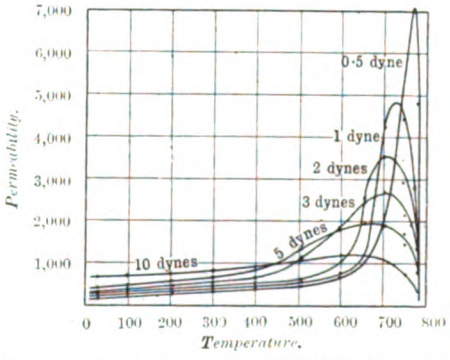

Fig. 1.—Varieties of Permeability with Temperature—Plate A—Unannealed.

with a tool. The rings had to be cut from the deposited plate by means of a rotating tube fed with emery dust, after which they were mounted in a lathe and ground into shape, the process requiring from two to three days for each ring. The dimensions of the rings were, roughly, as follows: external diameter, 3·5 cm., internal diameter, 3 cm.; height, 0·4 cm. One of the chief difficulties encountered was the problem of insulation between primary and secondary windings, since most substances which are good insulators at ordinary temperatures begin to conduct when heated, and a very slight leak is sufficient to give the galvanometer an uncertain drift, rendering accurate work impossible. The method finally adopted was to use rings cut from thin magnesia plates prepared by roasting the oxide between two plates of graphite in an electric furnace at a temperature of about 1,700°C. In order to ensure insulation between turns, a paste, made of fine magnesia powder and alcohol, was worked into the spaces, which, when dry, could be kept solid by careful handling. Another problem was the protection of the rings against oxidation. Since the magnetic properties of iron oxide are very different from those of metallic iron, and the cross-section of the specimen was always small, even a thin film would result in serious error. The first attempt to overcome this was to fill the furnace with an inert gas; but it was difficult to close the ends sufficiently tight, and even then the water of crystallisation of the mica, upon which the primary was wound, given up on heating, produced considerable oxidation. This difficulty was finally met by plating the rings electrolytically with copper. It was found that with a plate 0·7 mm. in thickness, a ring could be heated several times in perfect safety

Results.—Ten rings in all were studied, being cut from two different plates here called A and B. The iron in these two plates was quite

different, A having a finer crystalline structure and being much harder than B, both mechanically and magnetically. Rings cut from the same plate were quite similar, slight discrepancies being doubtless due to the difference in depth in the plate from which they were taken. Since the deposition of a single plate is a matter of several weeks, the unavoidable changes in acidity of bath and strength of current would necessarily result in non-uniformity of deposit. The results obtained are summed up in Figs. 1 to 3. Permeability-field strength curves at different temperatures were plotted for each sample, and the field giving the maximum permeability was determined from them. Its variation with temperature is given in Fig. 4.

To study the effect of annealing at temperatures higher than 800°C., a cylindrical box with a tight-fitting cover was turned from a bar of Swedish iron in which the ring to be tested was packed in finely powdered electrolytic iron. The ring could then be heated to any desired temperature with practically no oxidation, and at the same time be free from contamination with carbon. The time of cooling was about 24 hours. After each heating the ring was unpacked, re-wound and tested. The results are shown in the following table:—

Hysteresis Constants after Annealing at Various Temperatures.

Temperature, °C.	Energy loss.	Retentivity.	Coercive force.	Maximum induction.	Maximum permeability.
23	21,300	7,940	3·80	17,100	1,040
780	11,280	8,450	1·30	17,300	3,070
1,000	5,060	14,100	0·75	17,280	9,080
1,100	4,900	12,800	0·53	17,600	11,000
1,200	5,600	13,000	0·85	17,400	8,750
1,300	7,160	13,800	0·97	17,400	7,120

Experiments were performed on rings from plate B only, since it had previously been determined, that after annealing at 1,000°C.

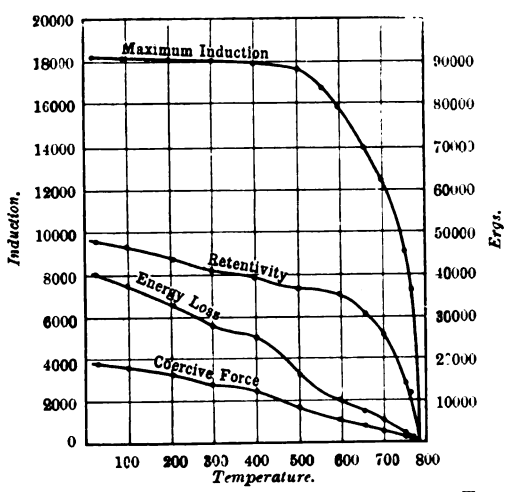

FIG. 2.—VARIATION OF HYSTERESIS CONSTANTS WITH TEMPERATURE. PLATE A, UNANNEALED.

all of the iron prepared by this process becomes practically identical. The field in these tests was carried to 80 dynes.

Before discussing these results, the author makes a brief digression on the temperature changes in the physical state of iron, upon which its magnetic properties so largely depend. According to Osmond, iron presents itself in three allotropic phases: Alpha, beta and gamma. Alpha iron is weak, ductile, ferromagnetic, stable below 785°C., and is characteristic of wrought iron and low carbon steels. It crystallises in cubes. Beta iron is weakly paramagnetic, stable between 785°C. and 890°C., and is probably hard and brittle. It is characteristic of certain self-hardening steels, also of normal carbon steel when hardened by sudden cooling, and like alpha iron crystallises in the cubic system. Gamma iron is stable above 890°C., is paramagnetic and characteristic of nickel and manganese steels. It is probably hard, but ductile, while its crystals are cubic with octahedral modification. The relations between these phases are best shown by means of the Roozeboom* diagram of Fig. 5, where the lines separating the different regions indicate the temperatures at which the transformations take place, when different amounts of carbon are present. Although the significance of this diagram is quite apparent, perhaps the field AaB requires special explanation, since it represents a mixture of the solid and liquid phases. The line Aa gives the greatest amount of carbon a solid solution may contain, while AB shows the least amount for a liquid; and any point, such as K, representing a given carbon content at a particular temperature, divides a horizontal line drawn through it into parts proportional to the relative amounts of the liquid and solid phases. As a molten mass of iron, containing 1 per cent. of carbon, for instance, is cooled, the point p represents the composition of the first crystals that are formed. As the temperature falls, the remaining liquid, being enriched in carbon, follows along the line AS until the temperature r has been reached, when the whole mass is solidified, the process having covered the temperature interval qr. The point B is called the *eutectic* point, and represents the combination which gives an abrupt solidification to a mixture of pure iron and graphite crystals. The line SED represents the formation of a definite compound Fe_3C, called cementite, while FL gives the transformation known as "recalescence" which consists of two simultaneous changes, the separation of the alloy of iron and carbon into alternate layers of ferrite, or pure iron, and cementite, and the transformation of the ferrite to alpha iron. The magnitude of the recalescence increases with the carbon content. The line MOSE is of special interest in this Paper since it corresponds to the disappearance of ferro magnetism.

Roberts-Austin* has studied the transformation points of electrolytic iron deposited from a solution of ferrous chloride by heating the specimen and determining its cooling curve. Besides the normal transformation points at 895°C. and 785°C., he found three others, namely, at 1,130°C., 475°C. and 270°C. The first of these had already been noted by Ball, and is of no particular interest in connection with this Paper. The second and third points he attributed to occluded hydrogen, and suggested that the one at 475°C. may be due to the separation of a hydride of iron from the solid solution, while the one at 270°C. is the corresponding eutectic point. He has further shown that by repeated heating in a vacuum, pumping out the liberated hydrogen, these points vanish. By making the iron the cathode of an electrolytic cell, it may again be partially saturated with hydrogen, when the point at 475°C. will reappear. These points are of special interest, for as pointed out later, certain changes in the magnetic properties have been found to occur near these tem-

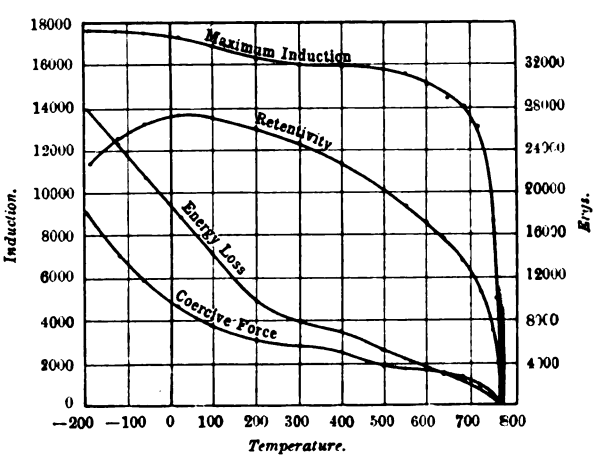

FIG. 3.—VARIATION OF HYSTERESIS CONSTANTS WITH TEMPERATURE. PLATE A, ANNEALED AT 800°C.

peratures. It is an interesting fact that the recalescence point' which is due to the presence of carbon, was found to be absent. Its absence in Burgess iron also has been shown in this laboratory.

Discussion of Results.—One of my first conclusions is that freshly deposited electrolytic iron is very hard magnetically, which agrees with the work of previous investigators. It is to be noted, however, that the magnetic properties of different samples are not at all uniform. In all respects, mechanically as well as magnetically, B is much softer than A, although they were prepared, as far as I am aware, under exactly similar conditions. This is not in agreement with the results of Leick, who found a marked uniformity in all samples, whether deposited from a chloride, sulphate, or ammonium sulphate solution. My results show, however, that these differences exist for small fields only, vanishing for fields of 100 dynes. I have found that after annealing at 1,000°C. they become practically identical for all fields. Some samples of single refined iron were much harder than either of these, one having a coercive for ce of 20 dynes. In this connection it would seem that Schild's criticism of Leick's results is not entirely justified. (Leick obtained results consistently higher than Schild's, obtaining for a field of 125 dynes an induction of over 19,000, while Schild obtained only 15,770. I have obtained 18,600.)

Plunging a ring in liquid air and leaving it for several hours produced no measurable permanent hardening. As the temperature is reduced below that of the room, the permeability decreases for

small fields, but increases for large fields, this effect being greater after annealing. The hysteresis loss continually increases as the temperature is lowered, the rate of increase being greater after annealing. This is entirely at variance with Fleming and Dewar's results on transformer iron, for they found no change in hysteresis loss at the temperature of liquid air. They also found the permeability to increase for all fields in the case of unannealed and hardened iron, which is again contrary to my results. A very curious effect is the decrease of the retentivity for low temperatures, giving a maximum of about 50°C. A careful search through the literature has revealed no mention of such a phenomenon, and it does not exist for several samples of commercial iron which I have tested. It is believed to be characteristic of electrolytic iron.

The temperature of transformation from the ferro- to the para-magnetic state has been found to be 785°C., which is in good agree-

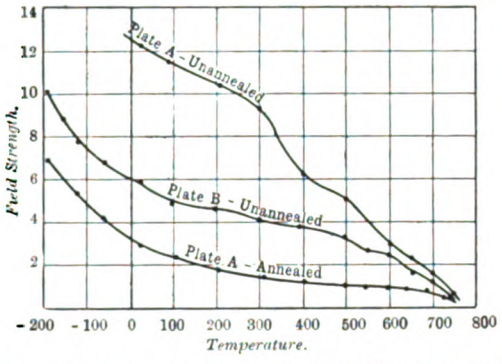

FIG. 4.—FIELD STRENGTH FOR MAXIMUM PERMEABILITY.

ment with the best data available on the temperature of transition from the alpha to the beta state. Hopkinson has obtained the following values :—

	Carbon content.		Temp. of transf.
Soft iron	0·01	per cent.	786°C.
Mild steel	0·126	,, ...	734°C.
Hard steel	0·962	,, ...	695°C.

Morris gives 780°C. for a sample containing 0·08 per cent. carbon. Referring to Fig. 5 these values are in accord with what we should expect from metallurgical considerations. Other experimenters have given values differing somewhat from the above, but unfortunately they have not included chemical analyses, hence their results are of little value for comparison. If the temperature were raised a few degrees above this critical value and allowed to fall slowly, magnetism always reappeared at the same temperature at which it disappeared. This seems to be characteristic of the purity of the metal.

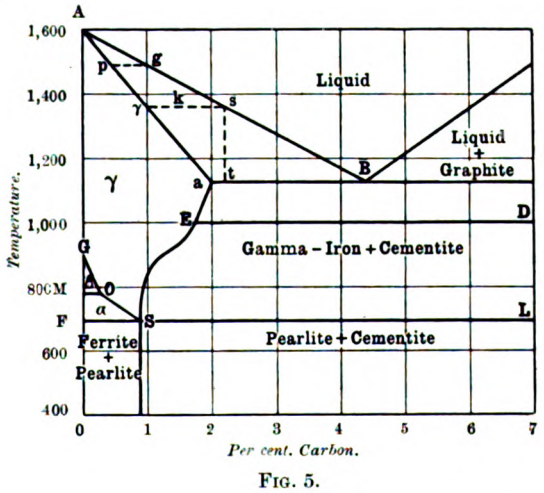

FIG. 5.

The change in the hysteresis loss with temperature shows some interesting variations. Kunz* concluded from his experiments on soft iron that hysteresis loss is expressible as a linear function of the temperature, while Morris' curves show distinct departures from a straight line. An inspection of Figs. 2 and 3 shows marked depressions just after the temperatures 300°C. and 500°C. have been passed. These are in accord with the hydrogen points of Roberts-Austin, already mentioned. It is worthy of note that sample A, after annealing, shows this effect to a less extent than before, a large portion of the occluded hydrogen having been driven off in the process. Perhaps a still more striking proof of the existence of these points is given in the curves of Fig. 4, where the field which gives maximum permeability is shown as a function of the temperature. As stated before, this point of maximum permeability was chosen by Ewing to mark the change from the second to the third stages of magnetisation, and the field at which it occurs furnishes a convenient index to the softness of the iron. It will be noticed that, in sample A, very marked depressions appear in this curve at the temperatures in question before annealing, but that after annealing, they can barely be detected. The changes in the magnetic properties at these temperatures can also be traced in the curves for coercive force and retentivity. Sample B, being much softer, and probably containing less hydrogen, shows this effect less. The corresponding curves of Wills for wrought iron and alloys show no such abrupt changes.

Probably the most striking effect, the variation of permeability with temperature (Fig. 1), is the sudden rise in permeability for low fields just before the transformation to beta iron takes place. The highest value of permeability which I have obtained is 11,000, occurring at a field of 0·5 dyne. Morris obtained a maximum of 14,600 for H = 0·2 in the case of Swedish iron, while Wills gives 17,200 for wrought iron for H = 0·172. Although this last value seems large, the comparison shows that electrolytic iron is not so soft as some commercial irons. The chief respect in which my permeability curves differ from those of Morris is in the matter of regularity. It is well-known to metallurgists that the transition from alpha to beta iron is not abrupt, but covers a considerable temperature interval, the temperature at which the transition begins being greatly lowered by the presence of impurities. The depression in Morris' permeability curves has been interpreted as marking the lower limit of this transition. In view of the fact that I have found no indication of such an effect in electrolytic iron, it would seem as though this depression cannot be characteristic of iron itself in changing from the alpha to the beta state, but must be due to the formation of a molecular combination of the iron with some impurity.

As to the effects of annealing at low temperatures, the maximum permeability is increased about 50 per cent. by heating to 800°C., while for small fields the increase is many fold. The results of heating to higher temperatures show that the iron is in its best state magnetically when annealed at 1,100°C. Further heating decreases the magnetic quality very decidedly. Comparing electrolytic iron with Swedish iron I found that while it has a slightly lower coercive force and a higher maximum permeability, its high retentivity gives it an energy loss nearly 60 per cent. greater.

Stansfield* has studied the physical changes that take place in iron when heated to temperatures that are high but insufficient to melt it. He recognises two stages, (*a*) overheated, (*b*) burned. The first refers to cases in which the temperature has not been carried above the line A*a* in the Roozeboom diagram. Although the point of incipient fusion has not been reached, there has been a marked diminution in the closeness with which the crystals are held together. He has given no lower limit for this stage, but from my results it would appear to be just above 1,100°C. The iron can practically be restored by annealing at a lower temperature. The second stage refers to cases in which the temperature has been taken above the line A*a*. A highly carburised liquid is here formed which accumulates in the intercrystalline joints, and if the metal is held at this temperature too long this is forced out by the carbon-monoxide gas which is formed, leaving interstices in which oxidation may take place. If there has been no oxidation the metal may be restored by reheating to a temperature a little above that represented by the line GOS, and cooling slowly, giving the carbon time to diffuse through the mass of the metal.

THE SINGLE-PHASE SERIES MOTOR.

In our issue of February 11th we gave an abstract of a Paper read by Messrs. W. S. Franklin and S. S. Seyfert before the American Institute of Electrical Engineers. In this Paper the authors suggested a striking departure from the standard design of single-phase series motors—viz., to employ an internal field, external armature machine, and to remove the commutator away from the motor. A very interesting discussion took place in connection with this suggested design, and below we give an abstract of the remarks of the various speakers.

DISCUSSION.

Mr. S. M. KINTNER thought that a comparison of the output of the proposed 500 H.P. motor, which the authors submitted as one that could be operated within the space limits of the present New York, New Haven

Digitized by Google

& Hartford Railway Co.'s locomotive motors, with one of those motors, showed that there was no gain in output per unit weight of active material. The attempt to gain had been made by dividing the motor up into two parts, one of which was made up of the magnetic circuit and inductors which occupied all of the available space at present used by the entire motor on the New Haven locomotives, and the other part, made up of the commutating device, with its necessary choke coils for keeping down the short-circuit currents, which the authors proposed to place in some convenient location outside the motor frame, and which had its own additional space requirement. With the proposition then that an increased output could be effected in direct proportion to the increase in active materials that could be placed in the available space, the discussion hinged on (1) the feasibility of the external commutator with revolving brush-holders, and (2) the value of balanced choke coils for limiting the short-circuit currents. In passing, he noted that, estimating the dimensions of the copper conductors from published I²R losses, the insulation allowances in the proposed 500 H.P. motor were much too small, there being but one-half that allowed in the armature slots of standard machines. Further, the method of getting the windings in place with the proposed slot, copper and insulation dimensions was by no means evident, and the number of commutator bars selected was such as to cause some difficulty in connecting the equalisers. He did not believe an external commutator with revolving brush-holders could be built for this class of service so as to be a commercial success. The difficulties involved were: (1) The construction of the commutator with its 504 flexible connections from the motor windings through the choke coils mounted on the locomotive cab down to the commutator bars, (2) the mechanical arrangement necessary for driving the brush-holders synchronously. It seemed well-nigh impossible to devise a satisfactory arrangement of this kind when viewed from the standpoint of reliability, accessibility for inspection and repairs, freedom from mechanical injury during overhauling other parts of the locomotive, first cost, &c. Again, the increased complication, cost and maintenance expense of the two sets of collector systems for supplying current to the brush-holders and to the rotating field were another serious feature of this type of motor. It would be very difficult to construct a drive which would be absolutely positive and not liable to any interruption, and which would maintain accurately for long periods of time the correct brush setting on the commutator. Single-phase commutator motors were very sensitive as regards brush setting, and great care was taken to insure a correct setting on the present types of such motors to within less than $\frac{1}{4}$ in. All the brush-holders if rotated at motor speeds would need to be carefully balanced, and the carbon springs would require some form of compensator on account of centrifugal forces which would otherwise cause unequal brush pressures. Many other difficulties suggested themselves, but the foregoing were sufficient to indicate the character of trouble that would be encountered. On considering the question of balanced choke coils for limiting the magnitude of the short-circuit currents, one was surprised to find how large these coils became. In connection with the 500 H.P. motor proposed by the authors, the voltage between consecutive commutator bars was not as great as that on the New Haven motors. The magnetic density in the various parts of the proposed motor was also somewhat less. From this it might reasonably be argued that the size of the choke coils and the motor power factor proved to be the limiting conditions which prevented an increase in output per unit mass of material. There were two other points that should be considered in connection with the choke coils, as determining factors of their value: (1) Their ability to withstand without injury heavy momentary overloads, and (2) the character of their construction combined with an adaptability for ready assembling in a suitable manner and at a reasonable cost. In considering the first point, an examination of the choke coil for the small machine shown in the Paper indicated that there was approximately as much resistance in the copper of the choke coil as would ordinarily be used in a regular resistance lead, and that this alone would have been sufficient to limit the short-circuit current without the inductive effect. This, then, indicated a serious sacrifice in sturdiness and overload capacity in order to keep down the size to such proportions as would allow the choke coils to be mounted inside the armature. The authors stated: "It does not seem possible, however, to produce a single-phase motor that will operate satisfactorily without the use of special devices for the prevention of excessive short-circuit currents." He wished to take exception to this statement, as it was perfectly feasible to build motors without any special devices of this nature, provided the induction per pole was kept low enough. There were a great number of motors of this kind in operation giving satisfactory service. Considering the second point, that of cost and adaptability for assembling, he had found on calculating suitable coils for the proposed 500 H.P. motor that the sizes were rather startling, and one was inclined to the belief that the authors were so glad to find a place large enough to accommodate the choke coils that the mechanical difficulties involved in the use of the external commutator looked small. The space available for the motor of a locomotive depended so much on the type of motor mounting and drive that comparisons on the basis of the output of different types were misleading.

Mr. E. H. Anderson thought the Paper brought out very clearly the difficulties of designing a single-phase commutator motor. The scheme of placing reactances so as theoretically to reduce sparking was ingenious. The criticism was that it did not make for simplicity. It appeared from the text that the leads of the stationary winding were connected into the stationary commutator, although space and details of construction were not shown. In order to take the motor apart for repairs, it was necessary to pull off a driving wheel, or separate the stationary member, and in this case it became necessary to disconnect the winding and all the commutator leads coming from the lower half. The driving mechanism for the revolving brush-holders must be positive and rigid. No slack or looseness could be allowed, for the exact position of the brushes on a single-phase commutator motor was very essential for proper operation and speed. Such a motor as described usually had about an 8 in. commutator and 18 in. of core iron between heads. The power of a motor was dependent largely upon the length of core, and if all the commutator length could be put into core—viz., by adding 8 in. to 18 in.—it became possible to increase the power about 45 per cent. However, all the commutator length could not be added to the core, for the reason that there must be a circular conduit at each end to allow the leads of the lower portion of the stationary member to be brought up to the stationary commutator. This would require approximately 3 in. on each end, thus leaving 2 in. to be added to the core length, giving 20 in. instead of 18 in., or an increase of 11 per cent. After the leads left the conduit they must be spread around the commutator and held firmly, as well as properly ventilated. Usually from a given space a certain amount of heat could be blown out, so that with a given efficiency only a given amount of work could be done in that space. The driving device for the revolving brush-holder rigging must take up some space on the axle. This would no doubt use up the spare 2 in., with the result that the iron core between heads was not increased. The serious question about the construction, to the speaker's mind, was that it was not the simplest. A prominent railway company built and installed a motor on a single-truck car, which should act as a counterweight to the real motor. The motor was a chunk of cast iron, with armature bearings on it, mounted outward on a single-truck car, and over-balanced the effect of the real motor, which was outwardly hung on a single-truck car. This was put on as it was thought the real motor might tip up end-wise and block the system. These motors were used for a long time, and gave no trouble, probably on account of their simplicity.

Mr. E. F. W. Alexanderson preferred to look at the subject in a somewhat different light rather than discuss the schemes presented in the Paper. The three principal limitations in the design of an alternating-current railway motor were heating, commutation and starting torque; of these three, the starting torque was, however, the most important. The first attempts to design the alternating-current railway motors were naturally along the same lines as those of direct-current motors. The motors were completely enclosed, and the service capacity was determined from the heating characteristics. As soon as forced ventilation was adopted in an alternating-current motor the whole basis of the design was changed, and heating was no longer the limiting feature. Commutation difficulties could be entirely overcome at any normal operating speed by application of a commutating field of suitable phase and strength. They could also be counteracted, to a great extent, by the use of so-called resistance or preventive leads. The ruling feature was, therefore, the starting torque. This applied to the three-phase railway motor, as well as to the single-phase railway motor, although for entirely different reasons. In the single-phase railway motor, the starting torque was limited by local heating on the brushes, commutator bars and certain parts of the winding. Various methods had been devised to increase the starting torque of single-phase commutator motors, and were agreed to be essential. The starting torque of the single-phase commutator motor was limited by the voltage per bar on the commutator, and the current per bar in the winding. Generally speaking, it could, therefore, be said that the starting torque was proportional to the size of the commutator. The special methods used to increase the starting torque consisted in providing means for either raising the voltage per bar or for raising the current per bar. In other words, both systems required space in the motor which could otherwise be usefully employed if the motor was intended for direct current. The scheme presented by the authors of the Paper was the first of the two mentioned principles for increasing the starting torque, carried to the extreme. The system was, according to the authors, very effective, but there was also every indication that it took room in proportion to its effectiveness, and there was no convincing evidence in the Paper that the space occupied by the motor with its elaborate non-sparking devices would not be quite as large as the space of a motor of more familiar design. The scheme, apart from its complication, did not solve the problem of space factor as it was worked out in the design shown in the Paper, because no provisions had been made for materially increasing the diameter of the commutator, which, after all, was a measurement of the starting torque. A natural solution was, however, given by the use of side rods which allowed the commutator as well as the rest of the motor to assume its necessary dimensions as well as its natural proportions. It was interesting to observe that the results obtained by the four or five manufacturers of single-phase railway motors in America and in Europe agreed closely in regard to weight and space per horse-power. In order to give some more concrete figures as to the space and weight factor of moderate size single-phase motors, the following data might be mentioned. A 25-cycle motor of the series repulsion type designed for 36 in. wheels had a weight of 5,900 lb., and delivered 150 H.P. at 600 revs. per min. in accordance with standard rating. This was in close agreement with recent developments of motors of several other types and makes. The various schemes employed for overcoming commutation difficulties could not, therefore, be judged by the space factor or the weight per horse-power. The nearest to a practical comparison was undoubtedly a test that had been embodied in the specifications for locomotives in connection with the contemplated electrification of two of the large western railroads, that the motor should be able to develop full torque at stand-still for a specified time, one minute or five minutes.

Mr. S. S. Seyfert thought that during the discussion the non-sparking devices proposed were assumed to be a necessary part of the inversion

Digitized by Google

of the relative positions of field and armature. It was not necessary, however, to use these choke-coils in the case of a motor with external armature, and as a matter of fact he had often thought that it might be desirable to use resistance leads only under certain circumstances, especially if the short-circuit volts were reasonably small. They had found it extremely difficult to design a motor of so large size with a reasonable short-circuit voltage per turn, for with a reasonable number of poles, say 12, the flux per pole on a 500 H.P. motor became so large as to produce 12 volts or more per turn on the armature circuit. He thought, however, that motors could be built on the resistance-lead principle that would commutate well enough, and in that case the stationary character of the armature, with the available space for placing the leads, would enable us to design the leads somewhat more generously, and therefore their liability to burn out at starting would be less, which would mean a lessening in the cost of repairs and an increase in the reliability of service. On the basis of resistance leads alone, dropping entirely the question of choke-coils, it would seem an advantage to have the leads so located that they could be easily and separately repaired. This would compensate for a great deal of the otherwise complicated arrangement. As to the length of commutator, one speaker had mentioned that the length of the commutator on the present New Haven motor was about 7 in. or 8 in., and in case of the removal of this commutator that space would be gained. If they attempted to build a 500 H.P. motor the commutator would be about a foot long. In that case, assuming the commutator on the motor concentric with the axle, they would gain a foot of space by removing the commutator. Should they decide to make the commutator concentric with the armature this 1 ft. of space needed would necessitate a greater driving-wheel diameter. It should be plain, therefore, that the increase in gross length of useful iron made possible by the removal of the commutator would be 12 in. instead of 7 in. or 8 in. as would be the case in changing a 250 H.P. motor. As to design, the inverted motor had, among others, the following advantages: (1) The long external yoke or armature core had to carry the effective armature flux only, whereas, in the old type of motor, the corresponding core had to carry the total field flux. (2) The placing of the armature externally allowed the use of a wider and shallower armature slot, resulting in a better commutation constant and a slightly better power-factor. The compensating slots through the poles must be deeper in this case, which condition might be easily met. Because of the comparatively low voltages at which single-phase motors must operate, it had been found somewhat difficult to satisfy the direct-current commutating condition on a motor of large size with such a small number of poles. (3) The air-gap periphery was somewhat increased in the case of the external armature motor mainly because the armature required less radial depth than the field. (4) The end-windings of the compensating coils were very much shorter, as was mentioned in the Paper. The authors had made some experiments on core losses in field and armature, which might be of interest. For some time they were under the impression that the core losses per unit of volume in the armature of the alternating-current motor should diminish as synchronous speed was reached. Upon going into the theory of the matter this seemed to be so, but for some reason the core losses actually increased somewhat with speed, and grew very rapidly above synchronous speed. This might be due to the fact that the losses caused by the bunching of flux by the teeth were such a large percentage of the armature core loss. In the Paper it was stated that they had selected the 10-pole type of motor; it was found later that 12 poles would have been better, and thereby they could make a better machine, one that would commutate better and have a smaller short-circuit voltage.

President STILLWELL said he did not propose to enter into the discussion, but one or two points had occurred to him. One was that the argument in favour of the increase of output in proportion to dimensions was greatest in the case of multiple unit equipment. In which case the Paper made no suggestion as to the location of the commutator and its leads. In the case of the electric locomotive, taking the state of the art as it existed when the New Haven locomotives were designed, the designers were undoubtedly cramped for room in attempting to place the motors underneath the floor of the locomotive. The tendency was now rather towards raising the motors and gearing to a shaft, in which case the argument in favour of separate commutator and its leads from the field armature was somewhat minimised.

Prof. W. S. FRANKLIN, in replying to the discussion, said in regard to the location of the detached commutator in the multiple-unit car, Prof. Seyfert and the speaker had considered that matter in some detail and came to the conclusion that a very great advantage would be realised by placing the motor on one side of the axle and the commutator on the other side of the same axle, taking the commutator leads across through a covered passage-way over or under the axle. In regard to the general question of detaching a commutator, a commutator was a switchboard, and it was proper to detach a switchboard from the machine which it controlled. In regard to simplicity, he pointed out that the motor under discussion was about the nearest approximation that he knew of to a "piece of cast iron." In answer to Prof. Kintner, the short-circuit voltage of the No. 5 (500 H.P.) motor was 12 volts per turn. As to the necessary size or carrying capacity of the individual choke-coils, it was stated in the Paper that a short-circuiting arrangement could be provided so that choke coils or resistance leads could be cut out or in at pleasure. Therefore, at starting, very high resistances might be inserted in the leads and these resistances might be cut out with increase of speed after starting. He wished to emphasise a point brought out in the Paper, namely, that one of the most important features in the suggested design was that it was possible to treat the problem of starting and the problem of running as two distinct and separate problems.

THE DETERMINATION OF THE EFFICIENCY OF CONTINUOUS-CURRENT MACHINES.

BY W. C. CLINTON, B.Sc.

Various modifications have been proposed from time to time of the original Hopkinson method of testing two similar machines.

These modifications have had two objects in view:—Firstly, the supply and measurement of all the power used electrically, and secondly, the realisation of exactly similar conditions of test for each machine. This second object becomes of importance if accurate values of efficiency are desired.

It is known that both conditions cannot be secured together, as the core and frictional losses can only be supplied by a torque from the common shaft. Recognising this, Blondel* has suggested a method of attaining the second object, by supplying the core and friction losses to two similar machines coupled mechanically, by the aid of a third motor, and the copper losses from a battery or dynamo in series with the two armatures, the field circuits of the two machines being separately excited to an equal degree. A disadvantage of this method is the introduction of the efficiency of the third motor, although the method gives the nearest approximation to a complete separation of the copper and core losses yet suggested.

If all the power is supplied electrically, as in Kapp's methods, the power represented by the core loss and frictional torques for the two machines must be supplied by the motor over and above that required for the dynamo output. The motor will be, therefore, always more heavily loaded than the dynamo.

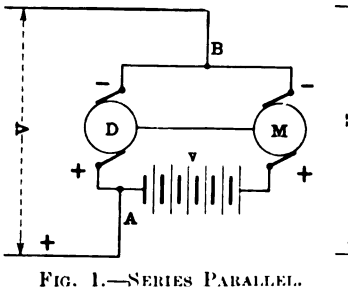

FIG. 1.—SERIES PARALLEL.

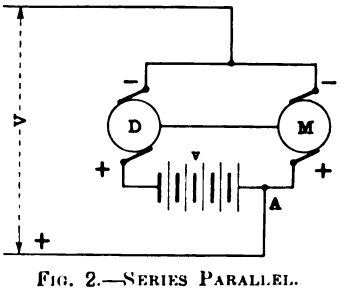

FIG. 2.—SERIES PARALLEL.

When the armatures are in series with the supply, the fields being separately excited, the difference between the field currents of the two machines must be great for light loads and must be diminished as a heavier load is required. This difference may be made to vanish or even change sign with interpole machines heavily loaded.

When the armatures are in parallel with the supply, light loads are obtained with the two excitations nearly equal, and the difference between the two excitations must be increased for heavier loading.

By combining the series and parallel arrangement as in Hutchinson's method,† the ampere-turns on the field of each machine may be kept equal, and at their normal value, over the whole range of loading, so that the full heating effect of the field coils on the machines is obtained. A careful comparison of the Blondel and Hutchinson methods has been made recently by G. Brion.‡

Two cases arise in dealing with Hutchinson's method. The constant voltage in parallel with the armatures may either be applied direct to the dynamo terminals, as in Fig. 1, or direct to the motor terminals, as in Fig. 2.

If the normal voltage is supplied at A and B, then in Fig. 1 the dynamo will be running at constant P.D. from no load to full load, while the motor voltage and the speed of the combination will be above their normal values. In Fig. 2 the motor voltage will be normal at all loads, and the dynamo voltage and the speed of the combination will gradually fall

* Blondel and Dubois, "Traction Electrique," Vol. II., 1898, p. 370.

Digitized by Google

from no load to full load. The connection in Fig. 2 is a good one to use if it is desired to realise working conditions for the motor.

To do this for the dynamo as a separately excited machine running at a constant speed and excitation, the contact A may be made at an intermediate point on the voltage v, when conditions intermediate between those of Fig. 1 and Fig. 2 will be obtained.

There is one position for the contact A which will give constant speed over the whole range of loading provided that V is constant, and at the same time will ensure that the drop of pressure at the dynamo terminals for a given current will be the same as that which would be observed for that current if the machine were on an actual resistance load.

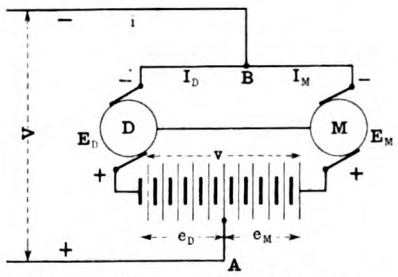

FIG. 3.—DIVIDED SERIES PARALLEL.
The battery v may be replaced by suitable generator separately driven.

Referring to Fig. 3, the loading is determined by v, that is, by e_D+e_M, the motor current I_M exceeding the dynamo current I_D by the current i. The position of the point A should be such that the internal E.M.F. of the dynamo is as much below V as the internal E.M.F. of the motor is above it. Let f be this defect or excess, then $V=E_D+f=E_M-f$.

V is also equal to $E_D-I_DR+e_D$

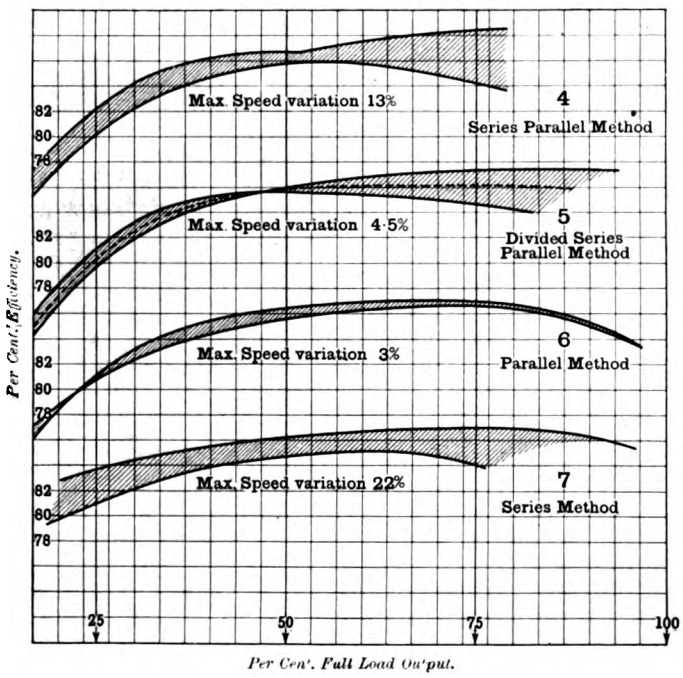
and $E_M+I_MR-e_M$,

where R is the resistance of the armature circuit of either machine.

It follows that $e_D-I_DR=e_M-I_MR$

or $e_M-e_D-R(I_M-I_D)=iR$.

The nearest approach to identity of conditions of test for two similar coupled machines, when the whole of the power



FIGS. 4, 5, 6 AND 7.

is supplied electrically, will be obtained by using the connections of Fig. 3 and arranging that e_M and e_D shall be in the above relation.

Usually iR is very small compared with e_M and e_D, especially at heavy loads, when i may become zero, or even reverse. It is therefore sufficient to make e_M equal to e_D. This is conveniently done by bridging v with two adjustable resistances in series and making the contact A at their junction, or using one resistance with a sliding contact, and making this the point A.

The curves shown in Figs. 4, 5, 6, 7 give the results of tests carried out on two similar shunt-wound interpole machines each rated at 6 kw. and 220 volts in the Pender Laboratory of University College, London. The machines were directly coupled together and were supplied with separate excitation of their shunt windings. These excitations were kept exactly equal throughout the tests, the results of which are shown in Figs. 4 and 5, at a value that gave the normal speed as a motor running light. The machines were loaded for the parallel test (Fig. 6) by altering the field currents by an equal amount on either side of their initial equal values. Different loads for the series test (Fig. 7) were obtained by altering the dynamo field and the applied voltage, the motor field being kept constant.

The efficiencies shown are for the rotating parts only, in all cases, the field losses being left out of account.

The method adopted for the subdivision of the total loss was the same throughout. Each armature was debited with its appropriate copper loss, including that of the interpole winding, and with one-half of the total core and frictional losses, obtained by difference.

The efficiency curves of the machines, either as dynamo or motor, lie within the shaded areas of Figs. 4, 5, 6 and 7. These areas are defined by four curves in Figs. 4 and 5 and by two curves in Figs 6 and 7.

In Figs. 4 and 5 each machine was in turn dynamo and motor; this accounts to some extent for these shaded areas being so much greater than that in Fig. 6, where only one curve was plotted for each machine. This was also the case in Fig. 7, where the great width of the diagram is an indication of the inferiority of the series method.

The mean value of the efficiencies at a given output by the divided series parallel method should give the true efficiency of the rotating portion of either machine very nearly, as the only difference between them under the conditions of operation lies in their internal E.M.F.s, the dynamo being as much below the normal voltage as the motor is above it. The dotted curve in Fig. 5 gives this result. The efficiency of the whole machine can then be obtained by allowing for the known copper loss in the separately excited shunt winding.

AN EXPERIMENTAL CATENARY LINE.*

Summary.—A description is here given of the equipment used by various contractors on an experimental catenary line in the U.S.A.

Since May, 1909, the Connecticut Co. has been conducting an elaborate service test of catenary suspension systems on a line between Middletown and Hartford, Conn. The total trial section is about 11,000 ft. long, of which 10,050 ft. are over the Valley Branch (steam) of the New York, New Haven & Hartford Railroad, and 950 ft. over public highways. The purpose of this installation is to develop the characteristics of commercial catenary line material. Six prominent manufacturers, the Ohio Brass Co., the Westinghouse Electric & Manufacturing Co., the Electric Service Supplies Co., the Electric Railway Equipment Co.(through Elmer P. Morris Co.), the Johns-Manville Co. (through the Johns-Pratt Co.), and the General Electric Co. were each requested to erect an installation of about 1,700 ft. of single catenary for wheel operation at speeds of 40 miles per hour. The messenger sag, the types and spacings of hangers and the general details of design and installation were left to the manufacturer, subject, however, to the following conditions: The poles were to be spaced 150 ft. apart on tangents and 75 ft. apart on curves with the nearest face of the pole distant at the level of the top of the rail, 10 ft. 6 in. from the centre line of the steam track and 7 ft. 6 in. from the centre line of the track in the highways. Bracket construction was specified for tangents, and both span and bracket construction for curves. For bracket work, the poles were

* Abstract of an article in the "Electric Railway Journal."

Digitized by Google

to have a rake of 6 in. in 24 ft.; for span work, 12 in. in 24 ft. With the exception of the General Electric Co.'s division, it was ordered that the trolley wire should be of No. 0000 grooved copper, and the messenger wire of 7/16 in. extra galvanised, seven-strand Bessemer steel. For experimental purposes the General Electric Co.'s section was equipped with a trolley wire of No. 0000 grooved mild steel and a messenger of No. 0000 hard-copper cable made of 19 wires, each of 0·1055 in. diameter.

Up to the present time the behaviour of this installation has been very satisfactory. In a few cases one of the types of mechanical clamps gave some trouble due to the working out of the short screws with which it was furnished. With these exceptions, the entire line continued to remain in first-class condition.

FIG. 1.—CATENARY TEST LINE. DETAILS OF THE DIFFERENT TYPES OF BRACKETS.

Installation of the Ohio Brass Co.—All of the construction is of the bracket type with a hanger spacing of 15 ft. The sag of the messenger wire is 4 in. for 75 ft. spans and 16¾ in. for 150 ft. spans. The distance from the messenger wire to the trolley wire at the messenger support is 23 in., at the centre of 150 ft. spans 6¼ in., and at the centre of 75 ft. spans 19 in.

The pole bracket is shown in Fig. 1. All the bracket arm castings completely surround the T-bar, and the support rod and insulator pin castings are adjustable along the arm. For convenience in erecting, the bracket is so arranged that the messenger wire can be lifted over the end of the arm without having to thread it under the support rod. The messenger insulator pin is known as type C.E., form 1, and is made of black japanned malleable iron. The base of the pin completely surrounds the T-bar to make accidental disengagement impossible.

The hangers (Fig. 2) have hinged clamp ears closed by a conical wedge screwing down into conical jaws. There are three types, as follows: C.A., form 1, with a loop-top strap hanger; type C.B., form 1, with a sister-hook-top rod hanger; C.D., form 1, saddle-top strap-hanger with a hinge at the ear. The pull-off hangers are of type C.A., form 1, having sister-hook-top, rod hanger, double-grip screw curve ear and a spool above the ear for the bridle. The anchor hangers, located at the brackets, are known as type C.B., form 1, and also have a sister-hook-top and rod hanger, as well as special half-ears of the soldered type with an eye at the butt end. From this eye a guy with a turnbuckle leads over the insulator to the anchorage on the next pole. No steady strains were used by this Company.

Installation of the Westinghouse Co.—All of the construction is of the bracket type with a hanger spacing of 37 ft. 6 in. on 75 ft. spans and 50 ft. on 150 ft. spans—in other words, two-point suspension is used on the short spans and three-point suspension on the long spans. The sag of the messenger wire is 3½ in. on the 75 ft. spans and 16 in. on the other spans. The distance from the messenger wire to the trolley at the messenger support is 20 in.; at the centre of the 50 ft. spans, 4 in.; at the centre of the 75 ft. spans, 16½ in.

The pole bracket is the maker's 3 in. I-beam design with upturned ends and ½ in. tension rod. Fig. 1 includes, in addition to the bracket

Digitized by Google

details of the various fittings, such as the steady strain and its clamping ear, main line insulator, insulator clamps, &c. The weights of the several parts are as follows: Bracket arm, without main line insulator or steady strain, 64 lb.; main line insulator, 4 lb.; steady strain with clamp, 14 lb.; clamping ear for steady strain, 0·8 lb.; total weight, 82·8 lb.

Fig. 2 shows the anchor hanger, the anchor clamp and the new rocker type trolley hanger. The anchor hanger is provided with

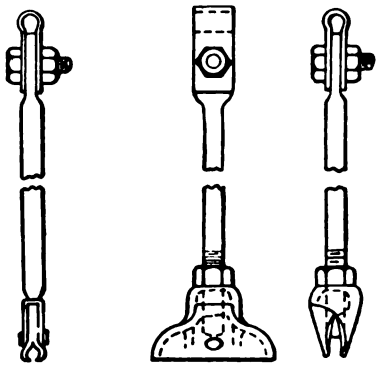
Westinghouse Co.'s Trolley Hanger, Pull-off and Anchor Clamp.

top. The trolley is tied to the messenger by an anchor clamp, which also ties to the messenger four head guys leading to adjacent poles.

Installation of the Electric Service Supplies Co.—The hangers are spaced about 15 ft. throughout. The sag of the messenger wire is 4 in. on 75 ft. spans and 16 in. on 150 ft. spans. The distance from the messenger wire to the trolley at the messenger support is 22 in.; at centre of the 75 ft. spans, 18 in.; at the centre of the 150 ft. spans, 6 in.

The brackets (*see* Fig. 1) are of the maker's T-bar type with an end-piece and tension rod. They carry Locke No. 5 A insulators for the messenger wire. The weight of a standard bracket equipment is 60·76 lb., distributed as follows: T-iron, 2½ in. × 2¼ in. × 9 ft. 6 in., 40 lb.; pole socket, with bolt, 2·13 lb.; two lag screws for pole socket, 0·22 lb. each; guy-rod clamp with set-screw, 2·63 lb.; guy rod and fittings, 8·17 lb.; cast-iron angle washer, 0·5 lb.; insulator pin and bolt, 5·36 lb.; and outer end ornament, 1·53 lb.

Two styles of hangers are used, known respectively as the "Interlocker" and the "Nuckelock" (*see* Fig. 2). The first is of the rocking type, consisting of stamped-steel ear-plates with interlocking fingers, a rod hanger with flat ends, a pin-hinged bottom and a saddle top; the second is of the rigid type with jaws rocking on a ball-and-socket joint and locked by means of a lug on one of



Electric Service Supplies Co.'s Interlocker and Nucklelock Hangers.

FIG. 2.—CATENARY TEST LINE. DIFFERENT TYPES OF HANGERS AND FITTINGS.

heavy clamp grips for the trolley wire and the messenger cable. The trolley wire jaws have eyes for the attachment of guy cables. The rocker hanger has two ears, each consisting of a pair of jaws screwing into a socket. These sockets are mounted at the ends of the rocker arm at the centre of which the hanger rod is connected by a hinge pin. The hanger is of the rod type, with flattened ends and saddle the jaws. The steady strains shown in Fig. 3 are used in curves only. An anchorage as made in the centre of the span consists of a single strain ear on the trolley wire either side of the centre, each having a guy with a turnbuckle tied to the messenger by a clamp anchor plate with four heads guy from corners of the latter to adjacent poles, as illustrated. No pull-offs are used on this section.

Digitized by Google

Installation of the E. P. Morris Co.—The hanger spacing is 19 ft. for 75 ft. spans and 30 ft. and 37½ ft. for 150 ft. spans. The sag of the messenger wire is 4½ ft. on 75 ft. spans and 17 in. on 150 ft. spans. The distance from the messenger wire to the trolley at the messenger support is 21 in.; at the centre of the 75 ft. spans, 16½ in.; at the centre of the 150 ft. spans, 4 in. The brackets are of galvanised double angles bent to clamp the pole, with a guy rod and a special three-bolt pole clamp, as illustrated in Fig. 1. The messenger is carried on Thomas No. 1,037 insulators. The steady strains are installed only on curves. Several specimens of span construction were installed as follows: One span with spool type insulators; four cases in which the span was made up with an eye-bolt in the pole head and porcelain goose eggs on either side of and close to the messenger; and the 10 remaining spans having wood strains instead of goose eggs.

All of the hangers embrace what the designer calls the "Sure Grip" clamp. This consists of two clamping jaws, a threaded and tapped stud and a compression cup and hexagon nut for locking all parts together and clamping the trolley wire. The locking is completed by bending down one of the small clinch points on the hexagon nut. The forcing nut acts directly on the 1 in. stud, so that no strain is imposed on the threaded end of the hanger rod. The clamp has no exposed threads nor pockets to retain moisture.

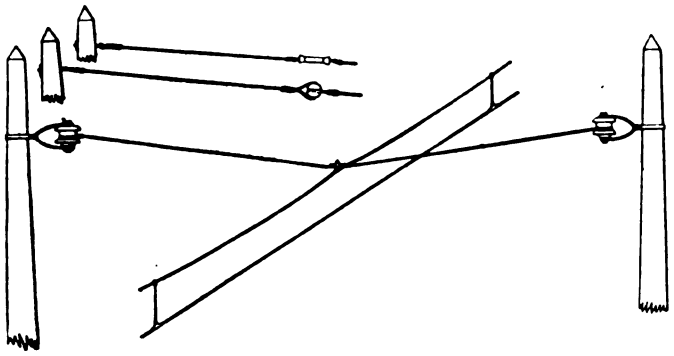
Electric Service Supplies Co.'s Span and Steady Strain Fixture.



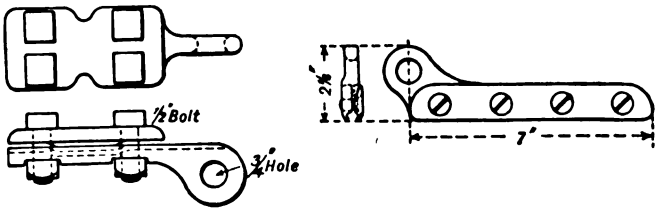
Elmer P. Morris Co.'s Three Types of Spans.

FIG. 3.—CATENARY TEST LINE. SPECIMENS OF SPAN CONSTRUCTION AND MISCELLANEOUS FITTINGS.

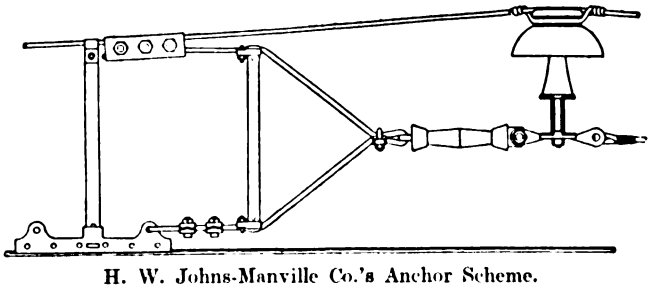
The straight-line hangers installed are of both the rod and strap types, including the clamp described and sister-hook tops. The sister-hooks are secured to the messenger wire and locked in place by two small clinching points. The latter are directly under the main holding points and when bent up in position serve to bind the messenger wire together instead of forcing it out of shape. The ½ in. suspension rod has a T-head which so engages the sister-hook that the rod can retain its perpendicular position by adjusting itself to the unequal expansion or contraction of the messenger and trolley wire. In the case of the straight line, strap type hanger the sister-hook top and the trolley-wire clamp are attached to the strap by ½ in. rivets, the whole making a very flexible suspension. The pull-off hangers are modifications of the straight-line rod hangers in having one or two eyes on the compression cup and in substituting one or two-eye messenger clamps for the sister hooks. The curves were pulled off with equal chords, the bridle being led back to a backbone stretched from pole to pole in accordance with the standard practice of the Connecticut Co.

On one side of a bracket an anchorage consists of a half-strain ear on the trolley with a guy led to a turnbuckle attached to a strain plate on the bracket and a guy wire clamped to the messenger over the strain ear also leading to the same turnbuckle. On the other side of the bracket guy wires from the opposite turnbuckle lead to the top and bottom of an anchor hanger. The anchor hanger illustrated (Fig. 2) is also used on curves. An anchorage on the span section consists of a two-clamp trolley ear, with a four-eyed compression cup at the top of the hanger rod. A guy wire is led from each side of the ear to the clamps on the messenger, and from the four-eyed compression cup guys are led in four directions to adjacent poles.

Installation of the Johns-Manville Co.—The hanger spacing is 10 ft., 12 ft. or 15 ft. for spans ranging in length from 75 ft. to 150 ft. The sag of the messenger wire is 5 in. on the 75 ft. spans and 16 in. on 150 ft. spans. The distance from the messenger wire to the trolley at the messenger supports is 20 in.; at the centre of the 75 ft. span, 15 in.; at the centre of the 150 ft. span, 5 in. One of the brackets is illustrated in Fig. 1. On curves the bracket is provided with a steady strain. It is 14 ft. long, and is composed of two rolled steel channels 2 in. deep and in 1. wide and weighing 2·6 lb. per foot. These channels are riveted together with spacing blocks between to increase the strength of the bracket as a strut. The blocks offer excellent means for fastening the various fittings by passing bolts between the channels and holding them in place with a washer, lock washer and nut. The tension rod is made of ½ in. hot rolled steel, having a head on one end and being threaded at the other. This rod passes up through a casting riveted between the channels, the head engaging the lower side of the casting. The tangent bracket differs from the curve bracket in being made of



General Electric Co.'s Messenger Clamp and Strain Clamping Ear.



H. W. Johns-Manville Co.'s Anchor Scheme.

FIG. 4.—CATENARY TEST LINE. PULL-OFFS, ANCHORS, &C.

two steel channels 3 in. deep and 1 in. wide pressed from ⅛ in. sheet stock. The tension rod is fastened to the bracket by a bolt passing through the two webs of the channels and an eye at the end of the rod. The messenger insulator is of the ordinary petticoat porcelain type with a malleable iron pin cemented into the porcelain. The pin is held to the bracket by means of a bolt passing up between the channels and screwing into the bottom of the malleable iron pin. Both flexible and rigid hangers have been provided, the former being of the bottom slide strap type with a two-screw ear and the latter of the rod type with a toggle clamp ear. The flexible hanger is made up as follows: The strap is stamped from steel stock 1 in. × ⅛ in. in section, a thickness which has been found stiff enough to prevent buckling from the blows of trolley wheels. Flexibility is obtained by a finger passing from one of the clamping plates through a rectangular slot at the lower end of the strap and through a rectangular hole in the other plate, the two plates being held together by flat-head machine screws. The strap is fastened to the messenger cable by a loop of flat stock, a bolt passing through the two loops and the upper end of the strap. In the rigid hanger the holding power of the trolley-wire clamp is secured by a pair of toggles. The weight of the trolley wire comes directly on the first point of the toggle arms so that the clamping effect on the wire increases automatically with the load. The nut and lock washers above the jaws prevent the opening of the latter with the upward pressure of the wheel. The messenger clamp consists of a malleable-iron hook screwed to the end of the hanger rod and having a grooved, hollow casting forced upward by a nut to hold the messenger firmly and to

Digitized by Google

prevent its slipping from the hook. Both flexible and rigid pull-offs are used, corresponding to the sections with flexible and rigid hangers. The flexible pull-off construction illustrated is used to avoid hard spots at pull-off points. Its messenger clamp consists of two interlocking plates clamping the messenger cable between them, the pull-off cable passing around grooves at the middle of the plates and holding them together on the messenger cable. The trolley wire is held by means of an ordinary single-curve yoke and curve clamp ear. A spacing bar is placed between the pull-off cables at a distance of about 15 in. from the line, beyond which they converge and fasten to a wooden strain. The rigid pull-off illustrated is made up of a steel tube with a clamp at the upper end similar to the messenger clamp of the flexible pull-off. The lower end of the steel tube is provided with a four-screw clamp ear. The pull-off cable loops around a shoulder at the lower clamp and loops over the two plates at the messenger cable. The steel tube is fastened to the messenger and trolley clamps by necks extending into the ends of the tube and being riveted to it. The two pull-off cables converge to a wood strain. The anchorage scheme is also illustrated in Figs. 4 and 5. The messenger cable and trolley wire are anchored to a plate held against the bottom of the bracket by the messenger insulator bolt. This plate is then anchored to the adjoining poles. The eye for attaching the anchor cable is placed far enough from the strain clevises to avoid the formation of a pocket to catch the trolley wheel. A spreader is placed between the cables attached to the messenger cable and trolley wire to avoid cupping the latter when the strain is applied. This construction also permits the use of a flexible hanger at this point to prevent hard spots.

Installation of the General Electric Co.—The hanger spacing varies from 17 ft. to 50 ft. The sag of the messenger wire is 6 in. for 75 ft. spans and 24 in. for 150 ft. spans. The distance from the messenger wire to the trolley at the messenger support is 30 in.; at the centre of the 75 ft. spans, 24 in.; at the centre of the 150 ft. spans, 6 in. Steady braces were not used on this section. In this installation the trolley wire is of No. 0000 grooved mild steel, and the messenger of No. 0000 hard copper cable, made of 19 wires, each of 0·1055 in. diameter. The brackets consist of two pieces of 2 in. × 1½ in. × ¼ in. angle irons, 11 ft. 6 in. long, joined at the extreme end by a space block and rivet, and by a second space block 2 ft. nearer the pole. The ½ in. steel guy rod which supports the bracket from the pole top passes through this second space block, the weight resting on the large button head on the end of the rod. The inner ends were sprung apart to span the pole and fastened with lag screws. The slot formed between the angle irons by the space blocks is used for attaching a malleable iron insulator pin to the bracket. The base of the pin is shaped to engage the slot and secured by a bolt passing up between the angles, thus providing means for transverse adjustment of the messenger with respect to the track. A standard single-piece, one-petticoat porcelain insulator, 4½ in. in diameter by 3½ in. high, was cemented to the pin for supporting the messenger cable. A piece of No. 8 iron wire was used for tying in. The end space block is provided with a lug which prevents the messenger cable from dropping off the end of the bracket in case the porcelain insulator is broken. It is also valuable during construction while pulling up the wires. In the span construction, the messenger support consists of two malleable-iron castings, one of which is

Digitized by Google

sprung on the span wire similar to a round-top hanger; the other casting having sister hooks for gripping the messenger cable is adjustable so as to accommodate the varying angles of the cross-spans. On curves this support was not located over the centre of the tracks, but directly over the trolley wire, the alignment of the trolley and messenger being made by the adjacent pull-offs. A wood strain insulator was inserted in the span wire 2½ ft. to 3 ft. either side of the messenger support.

The straight line hangers are of the flexible type and consist of a 3½ in. three-screw clamping ear, similar to the well-known screw clamp grooved wire ear, and a ⅛ in. cold rolled steel strap ⅝ in. wide. The supporting strap is bent so as to form an open loop 2½ in. long at the upper end, and is shaped to prevent the hanger from becoming unhooked, no bolts or clamps being used. The extreme lightness of these hangers, the heaviest weighing 8 oz., and the long loop allow maximum flexibility. The pull-off hangers are of the semi-flexible type, consisting of a 10 in. curve screw-clamp ear, a ⅝ in. stem and clamps for gripping the messenger wire and for adjusting the hanger lengths. The stem is provided with an eye at one end and a "T" at the other, the eye being bolted to a clevis on the trolley clamp to allow movement parallel to the trolley wire, and the "T" end is passed through the messenger clamp and limits the travel of the stem after a wheel has passed under the hanger. On curves of large radius appreciable flexibility is obtainable, and on small radius curves the adjusting clamp is used to maintain the proper distances between messenger and trolley. The loop hangers and the jointed pull-offs permit taking out the slack in the messenger and trolley wires independently.

The anchor scheme shown is designed to give maximum flexibility by avoiding hard spots in the line, and at the same time providing for the independent adjustment of both the trolley and the messenger wires. A special malleable iron two-piece clamp, with eye, was used for anchoring the messenger wire, and a single and soldered strain ear was employed for anchoring the trolley wire. A turnbuckle was used in each anchor wire, these, in turn, being attached to the bracket. The strain plate is fastened to the bracket by the insulator pin bolt. A separate plate is bolted to the bracket, from which the guys are run to adjacent poles. A space of 5 in. was left between the plates to avoid a pocket for the trolley wheel.

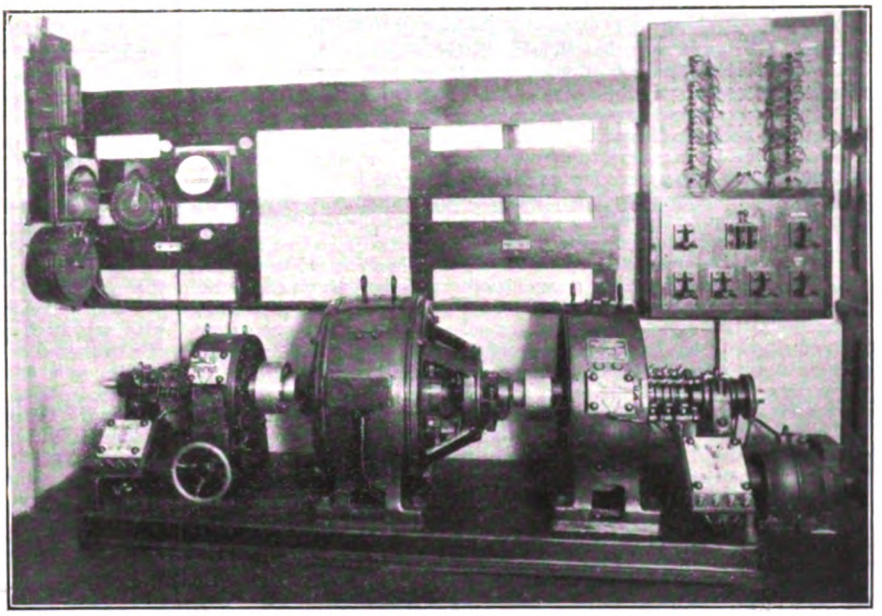
A special condition was encountered on this division and was overcome as shown in Fig. 5. The height of the trolley wire over the steam tracks was 22 ft., and after turning on the highway the wire descended while passing over a level section of 400 ft. to a height of 18 ft. above the rail. At this point ascending grades of 1 per cent. for a short distance and 5 per cent. for several hundred feet were encountered. It was desired to keep the height of the trolley wire 18 ft. above the track through this low section and up the grades. The whole structure tended to lift 12 in. to 18 in. Hence a pull-down was installed, located at the base of the 5 per cent. grade, consisting of a standard pull-off hanger guyed on either side to the poles supporting the span wires and pulling the wires down to the desired height above the rail. The weight of the structure was sufficient after the pull-down was attached to give the desired height above the rail at the base of the 1 per cent. grade. A hard spot is formed in the line by this method, but recent inspection shows no excessive wear upon the wire.

NEW TESTING SET AT THE MUNICIPAL SCHOOL OF TECHNOLOGY, MANCHESTER.

The latest addition to the already admirably-equipped electrical engineering laboratories at the Manchester School of Technology is a small testing set specially designed for testing meters and carrying out experimental work. This set, which was manufactured by the British Westinghouse Electric & Mfg. Co., and of which a view is given in the accompanying illustration, consists of three machines rigidly coupled together on a combined bedplate. It is driven by a 13 H.P. direct-current shunt-wound motor, suitable for operating on a 400-volt circuit. This motor is of the variable-speed type, and capable of running between speeds of 500 to 1,700 revs. per min., giving its rated output throughout this range. Two generators of the revolving armature type are arranged one on each side of the motor. These have ratings of 1 kw. and 5 kw. respectively, three-phase, 25 to 85 frequency, 100 to 340 volts at 500 to 1,700 revs. per min. Each machine is designed to give a sine wave, and is fitted with six slip rings. The motor is fitted with a terminal board arranged for connecting the field coils in parallel, as they may occasionally have to be excited from a lower voltage than 400.

The 1 kw. generator has its yoke machined on the outside and fitted into a circular seat on the bedplate, and is arranged with a worm gear for rotating the field. This enables the machine to be given a displacement of as much as 200 electrical degrees with respect to the 5 kw. generator. A gradual variation of phase adjustment is obtainable by this means while the set is running. This is necessary, as the phase has to be adjusted for each variation in current output on account of the varying lag with a varying current in the armature. By this arrangement it is possible to vary from maximum lagging to maximum leading current. Terminals are also provided for making easy and rapid connection with the external circuit.

The set is specially balanced, so as to run with no vibration and not to disturb the instruments in the standardising room in which the set is installed. The engineering staff are carrying out, by means of this set, a number of very interesting and valuable experiments on the effect of wave form, &c., on the indications of induction type meters.



NEW TESTING SET AT THE MUNICIPAL SCHOOL OF TECHNOLOGY, MANCHESTER.

ELECTRIC BRAKING ON THE GLASGOW CORPORATION TRAMWAYS.

Below we give an account of the discussion that took place last week at the meeting of the Institution of Electrical Engineers, when Mr. A. Gerrard read his Paper on this subject. An abstract of this Paper appeared in our last issue.

Mr. J. S. PECK (British Westinghouse Co.) said that Mr. Fell had shown very conclusively, both in his Paper before the Tramways and Light Railways Association in 1906 and in other communications since, that it was possible to obtain a brake which, with proper handling, would give as great a retarding effect as could be desired. There was, however, always the possibility of improper handling, and he thought that the device described in the Paper was one which eliminated as far as possible the human element. It was as skid-proof and as nearly fool-proof an attachment as one could ever hope to obtain. Having eliminated the human element, there was yet another element which had received scant attention in the past—namely, the effect of the braking apparatus upon the rest of the equipment. The author had shown very clearly that with rheostatic braking, and also with the old type of magnetic brake, very heavy currents flowed during the braking period. Those currents added very materially to the heating of the motor, and therefore to the rate of deterioration of the installation. The reason why the Glasgow Corporation had such extremely low maintenance costs for their tramway equipment was to a large extent due to the careful supervision which was given the equipment. Yet the author said that the bulk of the troubles and breakdowns of armatures and controllers were due to the

Digitized by Google

heating of motors during braking, and to the voltages generated when braking at high speeds. The new type of magnet gave a great reduction in the braking current, while the skid-proof or shunt-field device appeared to eliminate entirely the excessive voltage rise. He thought that if Glasgow—having already such a low cost of maintenance—found it a good commercial proposition to put in the latest type of magnet with the skid-proof device, the managers of other tramway systems should certainly consider the same procedure.

Mr. E. H. COCKSHOTT (Leeds Corporation Tramways) said he had been associated with the development of the brake referred to by the author as the 1908 type. The real name of this 1908 brake was the Maley electro-magnetic rail brake, of which 30 had been supplied to cars of the Leeds Corporation. They had now had three years' experience of them under actual running conditions and on the steepest gradients, and they also had had many Newell brakes with No. 21 magnets, as well as the latest type of this brake fitted with No. 25 magnets. The latest type of this brake was undoubtedly a very powerful one under favourable conditions. The trouble experienced with it was that at high speeds it became a most difficult matter to prevent the wheels skidding when the brake was applied, and also, contrary to the author's remarks, they did not find it satisfactory at moderate speeds. In fact, so many reports were received regarding passengers who complained of being severely shaken, due to the alleged irregular and jerky action of the brake, that it was decided to remove it. The coupling of the wheel shoes to the magnets certainly reduced the currents and voltage generated, if the controller were operated with great care, but should all the resistance be cut out, as generally happened in cases of emergency, it was evident that while the wheels continued to revolve there would be at equal speeds the same maximum voltage and current generated with the two types of brake. The trouble with the Newell brake was, however, that in such cases the wheels, having an excessive torque on them, commenced skidding, and continued to do so for some few seconds, during which time the sudden reduction in the braking force often caused a considerable increase in speed. In a test made at Leeds with one of these brakes on a gradient averaging 1 in 11, the speed attained previous to applying the brake was 26 miles per hour. On the application of the brakes the wheels ceased to revolve, and did not again reach their normal speed until the bottom of the hill was reached, a distance of about 130 yds. from the point where skidding commenced. He quite agreed that the solenoid device to some extent reduced skidding, but he thought, nevertheless, that the addition of such complications into the braking circuit might cause trouble under the rough usage it was likely to get in actual service. It would have been more useful if the author had given results of tests of the Newell brake and solenoid device at speeds exceeding 20 miles per hour. He also questioned some of the figures quoted for the 1908 brake, in view of the great number of similar experiments they had made, from which very different results were obtained. As to the tendency of this brake to skid, it had for some considerable time been one of the chief claims that the wheels never really skid unless the brake was outrageously misused, and even then it was of such momentary duration that the retardation was unaffected. Throughout extensive series of trials on this brake, in the presence of independent experts, it had invariably been observed that skidding was entirely absent. He could not agree with the author's remarks regarding the uneven retardation of the 1908 brake, because, provided the rheostat was regulated correctly, experience showed that the operation of the brake in this respect was all that could be desired. The Tramways and Light Railways Association's report, in fact, remarked on the delicate graduation of the stops made by this brake. In the summary of his Paper the author remarked that with a 1908 brake it was doubtful whether a solenoid would reduce the tendency to skid or ensure more even retardation. The speaker failed to see why such a device should operate differently with a 1908 brake from the way it did with the Newell brake. There had, however, up to the present been no need to consider the advisability or otherwise of adding any such device.

Mr. A. W. MALEY (Electro-Mechanical Brake Co.) said it seemed clear that the real purpose of the Paper was to make a comparison of the Westinghouse brake and the brake of which he was the inventor, denoted in the Paper as the 1908 brake, greatly to the disadvantage of the latter. It was very strange and unfair that the author had suppressed the name of the inventor, and not even let his Company know of the proposed tests. It also seemed difficult to know why the Paper had ever been written, as there were two brake investigation committees, one appointed by the Municipal Tramways Association and the other by the Tramways and Light Railways Association, both of which had been at work for the past three years. He believed they had not, in fact, concluded their labour, and their reports, which had been widely circulated, covered all the brakes tested by the author. Further, the author's tests were not even recent, having been made 15 months ago. He thought that the tests were of such a rough character as to be misleading, and in view of the very exhaustive tests with accurate recording instruments which were made at Leeds on behalf of the Tramways and Light Railways Association by Mr. Fell, and further tests by the Brakes Committee of the Municipal Tramways Association, he did not think there was any call for the present Paper, which surely could not pretend to anything like the same accuracy. The conclusions reached by the author were so different from those of the Brakes Committee that they should in any case be most closely investigated. The first part of the Paper, dealing with the Westinghouse old type of brake, was of general interest, as it emphasised what had often been said, that the power of that brake was very small. He thought the addition of a solenoid to this old type would be to restrict the brake to its own power, so preventing the motors doing the large amount of work necessary on the old brake if a good stop were required. It would be of interest to many to know that solenoid control was patented by Newell, the inventor of the Westinghouse brake, in 1900, 10 years ago. Yet the London County Council had not, he believed, more than two or three cars fitted with it, although the tests were made on the solenoid by Mr. Fell two years ago. Skidding was a very serious matter, because the motorman was absolutely helpless whilst it was going on. When a brake was skidding the retarding effect was roughly about one-third of that when the wheels were rolling whilst being braked to the fullest extent. He next drew attention to the unfair way in which the Glasgow tests had been carried out, and stated that the Paper was certainly not an impartial one. Mr. Maley proceeded to give his reasons, and invited contradiction to his statement that an interested person was present during the tests, whilst he (Mr. Maley) was not. (The time limit having been exceeded, the president invited Mr. Maley to communicate his technical observations on the Paper for inclusion in the "Proceedings.")

Mr. W. H. BOOTH said it was generally admitted that electric brakes caused a good deal of injury to the car equipment, and a great many engineers thought it desirable to have a mechanical stand-by to an electrical brake. He asked the author whether a magnetic brake was of very much service when a car left the rails. Also, was there any serious reason why cast-iron brake shoes, which were so much more efficient in a mechanical brake, should not be used with a magnetic brake if the resistance and coils were designed accordingly. He showed two slides illustrating the purely mechanical arrangement adopted in the Freund brake as an addition to a magnetic brake, and tried for some time on the Yorkshire (Woollen) Tramways. However useful the electric brake might be for light work, he considered that there should be some safeguard in the way of a mechanical equipment; and if a mechanical stand-by were an admitted necessity, why not work the magnetic brake directly off the trolley wire? Probably the cost of current would be less than the repairs to equipment which resulted from the so-called economy of using the motors to provide retardation, and the risk of de-wiring the trolley would not exceed the risk from failures with the present electrical methods.

Mr. H. M. SAYERS pointed out that neither the author nor any of the speakers had mentioned the outstanding difference between an electro-mechanical brake of the Westinghouse type and mechanical brakes acting either on the wheels or on the rails. The difference lay in the fact that with the magnetic brake one could get a retarding effect which was not limited by the available weight of the car. That was not the case with any mechanical brake. In the ordinary wheel brake the amount of retardation depended on the coefficient of friction between the wheels and the rails, and was a function of the weight of the car, the same being the case with the track brake, whether applied by hand, spring or air pressure. The brake shoes simply took some proportion of the weight of the car, and that was the limit of retardation that could be obtained. Numerically, 32·2 × coefficient of friction = retardation in feet per second per second. With the magnetic brake the force available was that of the magnetic attraction between the poles and the rails, the limit of which was the area of the pole shoes. There was practically no limit to the retarding effect that could be obtained, except as regards the comfort of passengers carried; but it was quite impossible by any kind of mechanical brake to rely upon anything approaching the 8, 9 or 10 ft. per second per second retardation that was available with the magnetic brake. The latter was a very marked advance on other systems of braking. He thought that the author was to be thanked for giving them such a long series of brake tests, which were very difficult to carry out. It was well known that brake tests by different people in different places did not give consistent results. However, he could vouch for the accuracy of the tests on the Maley brake at Leeds as he saw the instrument records of that occasion. The author's results confirmed the view that the magnetic type of brake was the best brake for conditions requiring frequent stops at high speeds under more or less emergency conditions, such as heavy traffic. The application of the solenoid control—which obviated the original difficulties of excessive current and voltage—added considerably to the electrical wiring and control apparatus. Mr. Fell, in his Paper, pointed out that the Westinghouse brake had to operate through an electric circuit containing a large number of electrical contacts. It was not only necessary that the circuit should be intact throughout the whole of the operation, but it was also necessary that the original resistance of that circuit should be very low, and that could only be assured by very careful supervision. He did not think that the magnetic brake was the best for the purpose of controlling cars down steep gradients. If it was used, however, there should be some means of applying it mechanically at the beginning of the descent.

Mr. H. E. YERBURY (communicated) considered it had been amply demonstrated that the rheostatic brake was unsuitable as a service brake, and although there were hundreds in operation at the present moment, the constant application of such a brake had a serious effect on the electrical equipment, and it should only be looked upon as an expensive yet effective brake for emergency stops. The development of the magnetic track brake, apart from the wheel brake shoes, was a step in the right direction, and, undoubtedly, solenoid control of the motor fields had given excellent results. It was regrettable that the author had confined his attention to one particular form of brake, as it would have been interesting to have comparative data concerning other well-known forms of magnetic track brakes, where auxiliary brake shoes were pressed down on the rails; but, presumably, the author desired simply to emphasise the fact that with solenoid control much less work was put upon the motors, and "locked wheels," which had caused so many serious accidents in the past, could now be avoided. Tramway engineers could not fail to agree with the points set out in the author's summary, and it appeared that it was only a question of time before brakes in general would be magnetically operated, and manual labour would be reduced as much as possible.

Digitized by Google

Mr. A. GERRARD, in reply, said that from his remarks Mr. Cockshott evidently considered the solenoid would reduce the voltage. The Paper was practically written to demonstrate the advantage of solenoid control. The solenoid in conjunction with the 1908 brake would, undoubtedly, reduce the voltage, but it would not prevent skidding, the reason being that the 1908 brake transferred a portion of the weight from the driving wheel to the track blocks. The reason why he had not carried out tests at 28 miles per hour was because they had no hills on which to get up that speed. In reply to Mr. Maley's question as to why the Paper was written, he was asked by the local section to write a Paper, and decided on the present one, as it was some time since a Paper on electric braking was read before the Institution. The tests were certainly rough ones, but he had no idea when they were carried out that they would be embodied in a Paper. He thought, however, that the apparatus used gave conclusive results. Neither the Westinghouse Co. nor he himself knew of the Newell patent when they started on the subject. He had not inserted the name of the Maley brake because he did not wish to. Mr. Booth's slides were irrelevent to the Paper. It was, however, the easiest thing in the world to have a mechanical attachment. Mr. Sayers' remarks as to the difference between the electromagnetic brake and the mechanical slipper brake were also irrelevant to the subject. The Paper dealt entirely with the equipment and tests at Glasgow, where there was no mechanical slipper attachment. Regarding the difference in surging at Leeds and Glasgow, the equipment at Leeds was quite different from that at Glasgow, and he could only deal with the Glasgow results. The reason he did not test the brakes on gradients greater than 1 in 13 was because they had no steeper gradients at Glasgow.

DEVELOPMENT AND OPERATION OF HYDRO-ELECTRIC PLANTS.*

BY H. L. DOHERTY.

Summary.—The author first deals with the relation of water power development to the conservation of natural resources, and then proceeds to consider methods to insure against interruptions of supply. Recent penalties for interruptions of service are discussed, as well as methods of charging, classes of service which can be advantageously supplied, the amount of power it would pay to develop, &c.

The object of this Paper is to call attention to certain features of hydroelectric work deserving of more general or more careful consideration than they have had heretofore, and to point out such work as can be carried on to advantage.

There is probably no other class of securities which deserves so well the support of the public as those issued by companies owning and operating successful water-power properties, and having a permanent and relatively non-competitive market. Except for the possibility of further development in heat engines which will materially increase their commercial efficiency, thus tending to reduce the cost of power from fuel, water-power plants will tend to grow more and more valuable, as it is improbable that fuel will ever sell at a lower cost, and more than probable that the cost will gradually increase. Compared with almost every other class of investment, a water-power plant is far preferable, the source of supply being, in the main, perpetual, although in some instances somewhat modified by timber operations and changes in meteorological conditions.

Probably the greatest stroke of statesmanship of the last national administration was the interest aroused in the conservation of our natural resources. Unfortunately, the efforts of the administration were either largely misdirected or very generally misunderstood in regard to water-powers. Immense amounts of power are daily going to waste. The tendency of the Federal Government, and of many of the State Governments, seems to be directed toward obstructing rather than encouraging the development of water-powers. This institute can do valuable work in educating the public as to the restrictions which should be made and the encouragement which should be given to enterprises of this character. The most pressing need in the matter of the conservation of our natural resources lies in the direction of conserving our various sources of fuel supply. Every undeveloped water-power means a constant unnecessary fuel consumption; and Government, both State and national, should remove as far as possible every unnecessary obstacle to water-power development.

Combination projects both for irrigation and power can often be made highly profitable where commercial success for either project alone would be impossible. It is, therefore, necessary that the engineer who has the responsibility of determining the value of prospective power developments should be proficient in the engineering of irrigation. This opens up to this Institute a necessary field of work which even now seems somewhat strange and a few years ago would have been entirely remote. Power and irrigation projects, wherein the power must be generated at one point and transmitted to another point, and there provide irrigation by means of pumping, is alone worth serious consideration.

The present state of the art in electrochemical processes is a factor which makes possible the profitable development of many water-powers. Still further developments along electrochemical lines may add materially to the value of water-power projects which now have no available market. Special attention should be paid to processes which do not require a continuous supply of current, thus permitting the utilisation of power from water which would otherwise run to waste.

Failure to realise expectations in regard to cost of development, amount of power to be sold, existence of market (or of market at the price anticipated) and reliable service has played an important part in the retardation of development of water-power projects. If we are to learn by experience, then the broadest possible discussion of these subjects is to be desired. It would contribute much to the ease of developing the now unused water-powers if these difficulties could be overcome, or if the public could be made to understand the degree of risk and the cause for the existence of the risk. Generally speaking, there is no more reason why anticipations should not be realised in water-power enterprises than in other enterprises, if the proper amount of investigation and preliminary work is done. Unfortunately, however, the engineering investigation to determine the cost of a hydroelectric power proposition, and the exact amount of power available, is often a very expensive matter, requiring data obtainable only as the result of measurements extending over a term of many years.

A confused condition exists in the popular mind in regard to the marketing of power. The inability of the public to understand this matter has been a great obstacle in the development of power propositions—and in this matter the electrical engineering fraternity has been more or less to blame. Cost of power is sometimes stated on a kilowatt-hour basis, and at other times on the basis of peak load, or what might be termed a capacity basis. Without knowledge of load factor, or simultaneous demand factor, figures stated in these different ways may prove very misleading. The problem of reliable service from long transmission lines is much further from solution than all the other problems that have done so much to contribute obstacles to rapid development. The best of engineering talent does not seem able to promise for a transmission line the same continuity of operation that can be secured from a steam plant located at the point where the power is to be used, and this introduces many serious obstacles to the development of our water-power projects. The importance of continuity of service varies in degree with almost every customer served. To some industries a mishap which causes even a fall in voltage or a change in frequency may be a serious matter.

The author next considers in detail the following matters which deserve further thought and consideration by engineers connected with water-power work:

Methods to Ensure against Interruptions or to Lessen their Harmful Effect.—With reliable reverse circuit-breakers the linking up of several hydroelectric plants offers some insurance against interruptions. If central-station companies are to be supplied, it might sometimes be commercially practicable, where the available market greatly exceeds the capacity of the plant, to run the transmission lines to several central stations, with the idea that no one of the stations will attempt to take more than a portion of its base load, and will always have some steam apparatus in operation, the capacity of which can be quickly increased to take care of any interruption of service from the hydroelectric plant. In a recent power negotiation, where the supply was to be furnished from two hydroelectric plants, it was suggested that one of these plants should be run in connection with a steam turbine, the generator normally be run as a motor and the water-wheel governor arranged to open the steam valve to the turbine if the speed fell off perceptibly. The vacuum on the turbine blades is maintained to reduce the windage loss. In such cases the steam turbine, or water turbine, could be driven with a small amount of steam, or water, and the fields of the generator magnetised so that the load would be promptly picked up in case of interruption to service. This latter method, however, would be relatively less economical than to drive electrically, using steam or water only when service from the unit was demanded.

Equipment to Ensure against Interruptions or to Lessen their Harmful Effect.—It is customary on all important transmission lines to use either two circuits on the same pole line or two circuits on its own pole line. The latter plan is far preferable. Perhaps greatly added reliability could be secured by the use of extra conductors on each pole line, with effective switching apparatus that would enable the extra conductor to be brought into use as quickly as possible,

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

The use of storage batteries immediately occurs to one as a protection against interruptions, but their high investment cost and high cost of maintenance make them practically prohibitive when used purely to prevent interruptions of service. Gas engines would be almost ideal, but the high investment charges make them practically impossible. They, however, have been adopted in one or more instances. Gas storage can be provided at a cost of approximately £10 per 1,000 cubic ft., with no operating stand-by loss. This means an investment of about £80 per 1,000,000 B.T.U. for producer gas, or £16 for coal gas, and less than £14 for California oil gas. Where producers are used, if the fires in the producers are maintained in proper condition, no storage capacity is needed; and perhaps no other similar class of apparatus can be run with such a small stand-by operating charge as a gas producer. Unfortunately, however, a gas-engine power station represents such a high first cost that, in spite of the higher efficiency of the gas engine and the lower stand-by losses of the gas-generating apparatus, the commercial cost for purely relay service is higher than for steam equipment. If provision must be made for protection to service, a modern steam equipment offers about the lowest commercial cost.

The boilers chosen should be able to have their fires withdrawn without causing leaks, and should have the least stand-by loss in relation to their maximum capacity. Ordinarily we choose the boilers having the least consumption of fuel at full load, but for relay service we want the boiler having the least consumption of fuel at no load. It is the writer's opinion that for this class of service the internally fired boiler deserves careful consideration, but perhaps only in a modified form. This type of boiler, however, would be apt to be limited before other limiting features were reached by the lack of flue-gas conductivity of its fire tubes, which could be compensated for by a high draught pressure, but better compensated for by a modification in design.

If boilers are not to be run banked, but are to be fired up if an interruption occurs, the methods to be used for quickly starting the boilers are of great importance. The uses of oil for fuel probably ensures the greatest speed in tarting up, but this fuel is often prohibitively expensive. It is, however, possible to use oil simply as an auxiliary in the starting of the boilers and then substitute coal, either hand fired or machine fired. The writer does not remember ever having seen the suggestion made that powdered coal firing be used for this class of work. Powdered fuel is almost the equivalent of oil or gas, and is ideal for the class of service under consideration.

In the choice of steam engines the steam turbine would seem to be the only one worth consideration. The total first cost of steam turbines, including building, foundations, &c., should alone be enough to warrant their adoption; and if it were decided to run the engines idle, but with the fields of the generators magnetised, the steam consumption should prove materially less than for any other type.

Penalties for Interruptions of Service.—In a recent negotiation for the purchase and supply of power between a central-station company and a hydroelectric supply company, the question of continuity of service was given serious and detailed consideration. As ensurance against excessive interruption was being sought, and as the only ensurance possible was that to be obtained through operation of the steam plant, it was decided that ensurance should be obtained by running the steam plant (fully energised and ready instantly to take the load in case of interruption to the hydroelectric service) at such times and for such lengths of time at a stretch as might be necessary to ensure against interruptions coming oftener than at certain intervals. For example, to take an extreme case of the simplest form, suppose it had been decided that no interruptions of any kind whatsoever were permissible more than twice in any 12 months. Then, after any interruption, the steam plant would be run for six months, ready to take the load at any time in case of failure of the hydroelectric supply. This would ensure only two interruptions per year.

As the above assumes that a steam plant is never subject to failure, an allowance mentioned later has to be taken into account. As all interruptions are not equally disastrous, allowance was also made for both the length of interruption and the damage to different kinds of service, as follows: The load of the central station was divided arbitrarily into two classes, which we will call class A and class B. The power and the business district load together were considered as class A, requiring the greater ensurance against interruption, and the residence load as class B. The central station company demanded that the length of time which the steam plant should be run after any given interruption should be fixed with reference to the duration of interruption and to the number of interruptions which had occurred during the year preceding and up to and including the interruption in question. If the interruption in question was the first during said year, then the steam plant should be run of sufficient capacity to carry the class A load for 10 days for the first minute (or less), plus an additional day for each additional minute of duration of interruption; the time of running for each succeeding interruption to be compounded 20 per cent. That is to say, for the

First interruption	10	days plus	1	day per additional min.	
Second „	12	„ „	1·2	days „	„
Third „	14·4	„ „	1·44	„ „	„

and so on. Also that at the same time sufficient additional capacity of steam plant should be run to carry the class B load for 10 days for the first minute (or less), plus an additional day for each additional minute of duration of interruption; the time of running for each succeeding interruption to be compounded 10 per cent. That is to say, for the

First interruption	10	days plus	1	day per additional min.	
Second „	11	„ „	1·1	days „	„
Third „	12·1	„ „	1·21	„ „	„

In case an interruption should occur before the ensurance feature had been entirely worked out on a previous interruption, then the remaining days of operation of the steam plant for the interruption previously experienced should be discarded and a fresh start made for another run of the steam plant, just as though the new interruption had occurred after instead of during a running period. It was further provided that for the first two interruptions experienced in the 12 months period, the steam plant was to be run at the expense of the central-station company, on the assumption that two interruptions might occur even if the supply were from the steam plant alone. The expense of all subsequent operation of the steam plant was to be borne by the hydroelectric company.

Many other methods of penalties and ensurance are in vogue, but as this plan is believed to be new it is submitted for discussion and for comparison with other methods already known to the members of the Institute.

Methods of Charging.—While not always recognised, the cost of operation will be influenced, not only by the load factor but by the form of the load curve. Similar load factors do not necessarily mean the same cost for current, unless the shape of the load curve is the same. While the value to the user of the service of the hydroelectric company as compared with his own source of supply depends largely upon his absolute peak, the cost to the supplying company depends primarily on the demand of this consumer at the time of the hydroelectric company's simultaneous peak. Non-coincidence of maximum demands is, however, a legitimate source of profit to any supplying company, and this non-coincidence of maximum demands is generally a primary source of profit to the supplying company. In each case, however, the value of the service to the consumer and the cost of service to the producer depends primarily on the capacity demanded and the amount of current used. This is assuming that we are dealing with relatively large consumers.

In central-station practice large numbers of consumers are eventually connected having so small a current consumption and maximum demand that what might be termed the "consumer charge" assumes so much greater importance that it cannot be neglected. In fact, the condition has been reached where a large group of central-station consumers requires a greater investment and maintenance expenditure for meters alone than is required for the generating equipment necessary to supply them.

It is unfortunate that it is not better understood that there is more than one factor which goes to make up the cost of electric service. Talking of power in terms of charges per unit of demand only, or in terms of kilowatt-hours only, has led to much confusion and many costly blunders. If capacity and current were not jumbled together, and if the value and cost of each were better understood, it would do much to contribute to further development of electric service sales. The capacity cost to supply many consumers is far greater to the hydroelectric company than would this same cost be if the consumer supplied himself. On the other hand, the cost for current to the hydroelectric company is generally very small compared with the cost to the consumer were he to supply himself. The capacity the consumer should pay for should generally be based upon his absolute maximum peak experienced at any period throughout the year. Any other method of arriving at the capacity charge is apt to lead to great inequities.

Classes of Service which can be Advantageously Supplied.—If we were to assume that the maximum demands of all consumers occur simultaneously, then it is apparent that a point is apt to be reached where the total cost of service for any consumer is greater to the hydroelectric company than would be the cost of service to the individual consumer were he to supply himself, because, if the capacity cost is greater, there may not be enough current sold at the price charged to overcome the higher cost for capacity. Many consumers

Digitized by Google

could therefore supply from their own plants all, or a portion, of their demand, over and above their average demand, at a cost to themselves less than to the hydroelectric company.

By securing a number of consumers of a diversified character, even though more transmission lines are necessary, a good load factor can often be secured in spite of the fact that the individual consumers may have poor load factors; and by getting consumers to adapt their operations to the ability of the hydroelectric company to supply—that is to say, by some form of "limited service"—this same end can be realised. The future situation in the hydroelectric supply business will, however, eventually be that of the market greatly exceeding the supply, and the natural remedy will be the installation of steam plants by the hydroelectric companies to enable all possible available water to be used. Central-station steam-power plants have been made a success in competition with individual steam plants, and the success of steam plants in connection with hydroelectric plants should be even more pronounced.

How to Develop the Market Selected.—Few people seem to realise the costliness of tardy operations. A completed plant with an undeveloped load can create a deficit of expected earnings which will require many months of subsequent operations to wipe out. If the writer were to attempt the development of many of the large prospective water power undertakings, the transmission lines would be completed at the earliest possible moment, regardless of when the hydraulic generating plant could be put in commission; and if steam plants could not be taken over from prospective consumers to give in the aggregate enough capacity to carry on the development of the load, a relatively small steam plant in connection with the initial development of the water-power plant would be installed new, and would be added to as rapidly as required to ensure a proper load when the hydroelectric generating station was placed in commission.

The Amount of Power it would Pay to Develop.—It is the writer's belief that hydroelectric companies will eventually develop and sell all of the power that can be generated economically. To do this, in the absence of extensive reservoir capacity, will necessitate a heat engine auxiliary plant to supplement the hydraulic plant during low-water periods.

As to the maximum development, let us assume a hydroelectric scheme having simply a dam from which the water immediately enters the turbines and is immediately discharged to the river below the dam without any expensive canals, flumes, &c. Hydraulic apparatus can then be installed for carrying the peak load at a very much lower cost per kilowatt of capacity than by the use of steam. Not only this, but in this character of development all inequalities of load should be taken care of by the hydraulic plant; and if it is necessary to run steam plant, the steam load should be run for such time, and at a uniform rate, as will secure the most economic generation of steam power. Steam plants or steam units can be started up and shut down only at considerable expense, while water units can be started up and shut down at practically no expense.

In the character of development used above as an example, with a market which far exceeds the water supply, and where the price of fuel is relatively high, the hydraulic capacity installed can be equal to the maximum four days' supply of the stream. That is to say, the operation of a water turbine for 100 hours per year will, in some cases, warrant its installation. Under present practice most of us are only developing the so-called secondary power, which can be secured for a period of 10, or at least 8, months.

Depreciation.—The writer does not wish to appear as viewing the water-power problem from a purely financial standpoint, but still it is the financial standpoint which determines whether a water power shall or shall not be developed. Practically all of the present assumptions for depreciation are too high, and consideration should be paid to what the plant comprises.

Methods to Determine the Accuracy of Engineers' Estimates.—Without anything new to offer, the writer desires simply to lay stress upon the point of greatest value. Checking and re-checking plans by the same or other engineers may not disclose omissions or errors, while complete independent reports by two or more separate engineering corps, and the comparison of these reports, will practically ensure against all omission and all miscalculations, making it possible to do the development work for the cost anticipated with a realisation of all the power and the expected market at the price predicted.

It is hoped that the discussion which this Paper may provoke will bring out much of value to further the development and operation of hydroelectric plants and lead to effective future work along these lines. The problem is worthy of consideration from many different points of view. The whole public has been aroused by and applauds the movement to conserve our natural resources. Nothing can contribute more to this desired end that the speedy development of our water powers.

THE ELECTROCHEMICAL EQUIVALENT OF SILVER.*

BY F. LAPORTE AND P. DE LA GORCE.

The results of the three last researches published by Smith, Mather and Lowry (National Physical Laboratory), by Jaeger and von Steinwehr (Physikalisch-Technische Reichsanstalt), and by P. Janet, F. Laporte and P. de la Gorce (Laboratoire Central d'Electricité) are given in the following table:—

National Physical Laboratory	1·11827 mgm.	per coulomb
Reichsanstalt	1·11818	do.
Laboratoire Central	1·11863	do.

In compiling this table the original values have been corrected so as to express the electrochemical equivalent in terms of the units of resistance and E.M.F. used at the National Physical Laboratory. The last international conference having defined the ampere by the deposit of silver, a difference of 4 parts in 10,000 such as appears in the table was inadmissible.

Thanks to funds placed at M. Janet's disposal by the Scientific Research Fund Committee, a fresh series of measurements was carried out at the Laboratoire Central from June to December, 1909.

The test arrangements and method of working were the same as in the previous research of the Laboratoire. Two voltameters in series were, however, generally used with a view to facilitating the comparisons. The current density was about $\frac{1}{3}$ ampere, the duration 5 to 6 hours, and the mass of the deposit 7 to 8 grammes. During an experiment the current was kept constant within 2 parts in 100,000. The anode was placed in an envelope formed of a sheet of filter paper, evenly folded so as to prevent any particles of the anode from reaching the cathode. The filter paper used was that supplied by Schleicher and Schüll (No. 595, chlorine free). The authors have also employed a voltameter composed of a small silver bowl as anode placed alongside a like bowl, of platinum, as cathode, the two bowls being connected by a glass syphon 4 cm. in diameter. In this case great difficulty was found in maintaining the constancy of the current owing to the heating of the electrolyte. The mean of three experiments seems to indicate that the mass of the deposit thus obtained is greater by 1 part in 10,000 than when the filter paper form is used.

Purification of the Silver Nitrate.—The authors have tested electrolytes made with silver nitrate purified by various processes. As a general rule, only the quantity of salt necessary for a single experiment was treated at one operation.

Sample (1) was crystallised at reduced pressure and at a temperature between 30°C. and 40°C. After two crystallisations, the solution, prepared immediately before the experiment, was decanted into the bowl of the voltameter.

Calculating the results in terms of the English units (which were chosen for the purpose of rendering the results comparable), the authors found as the mean of eight experiments:—

Electrochemical equivalent of silver: 1·11827 mgm. per coulomb, the maximum variations from this mean being −13 and +8 parts in 100,000.

Sample (2) was crystallised by evaporation over a water bath. This method of purification, employed in the previous experiments at the Laboratoire Central, had led to results which were too high by 3 to 4 parts in 10,000, doubtless because the precautions taken either for the purification of the salt itself or for the preservation of the purity of the solution during the whole of the experiment were insufficient. The concentrated solution of silver nitrate appeared to absorb the impurities of the air easily.† By taking care to cover the solution so as to avoid prolonged contact with the air, and by purifying the salt by two successive crystallisations (the mother liquor being decanted and the crystals washed), the authors obtained as the mean of four experiments:—

E.C.E. = 1·11831 mgm. per coulomb, with maximum variations from the mean of −6 and +14 parts in 100,000.

Sample (3) was from Dr. Glazebrook, Director of the National Physical Laboratory. He sent the authors some silver nitrate from his laboratory, which gave the normal result there. This salt, used in six experiments, gave:—

E.C.E. = 1·11827 mgm. per coulomb, the maximum differences from the mean being −6 and +8 parts in 100,000.

Sample (4) was prepared by M. Etaix, Chief Demonstrator in Chemistry at the Faculty of Sciences, Paris. He purified some silver nitrate by crystallisation, the solution being evaporated in a

* Translated and slightly abbreviated from the "Comptes Rendus de l'Académie française des Sciences."

† A solution of nitrate left for 30 minutes in an atmosphere laden with tobacco smoke, and then employed in the voltameter, gives a deposit which is 5 parts in 100,000 above the mean value.

Digitized by Google

vacuum at ordinary temperature. The result of four experiments has given :—

E.C.E. = 1·11832 mgm. per coulomb with maximum variations from the mean of −11 and +7 parts in 100,000.

Sample (5) was commercially sold as "pure" and tried in two experiments. It has given 1·11825 as the silver constant.

Conclusion.—These experiments show that the improvements introduced into the purification of silver nitrate have caused the disappearance of the difference of 4 parts in 10,000 which existed between the authors' 1908 experiments and the measurements of the National Physical Laboratory. Thus the figures obtained in France, England and Germany appear to agree satisfactorily.

The general mean of the Laboratoire Central results is 1·11829, the English units, as already mentioned, being employed.

TESTING OF INTERMITTENT MOTORS.

We give below an account of the discussion which took place at the meeting of the Yorkshire local section of the Institution of Electrical Engineers when Dr. Pohl read his Paper on this subject. An abstract of this Paper appeared in our issue of March 25th.

Mr. W. Hartnell, in opening the discussion, said the importance of this subject was by no means exaggerated. The ordinary testing of enclosed motors was most unsatisfactory and the statements regarding them made by various makers were misleading. Dr. Pohl had put the matter forward in almost abstract form, but it was one of those subjects which did not lend itself to an abstract discussion. In abstract reasoning on a complicated subject one should be able to ignore many facts, as being of minor importance, in order to deal clearly with the main matters. Here the difficulties of obtaining a formula or mode of testing that would enable the final temperature of an enclosed motor to be predicted from a brief test seemed almost insuperable on account of the many unknown variables of almost equal importance. He had investigated this subject from an experimental point of view, and had given some of the results in a Paper on "Heating of Ventilated and Closed Motors" ("Proceedings," I.E.E. Vol. XLI., 1908). He agreed with Dr. Pohl wherever the latter had touched on practical points. The speaker found that although the heating and cooling curves of different sizes of motors had a general resemblance they were far from identical. The larger the enclosed motor the higher the final temperature. Thus he was forced to the conclusion that no large, totally enclosed, unventilated direct-current motor could be run at full-load continuously. Dr. Pohl stated that the heating and cooling curves approximately represented the logarithms of the ratio of two factors. This might be so, but the factors themselves were involved quantities, only discoverable by experiment. The speaker asked the author to give complete heating and cooling curves of, say, two enclosed motors. He entirely agreed with the author that from such curves the final temperature of a motor under intermittent loads could be found by means of a zig-zag line such as shown in the Paper. Practical engineering obliged us to search for truth by statistical methods where the result depended on many indeterminate variables. Having experimentally obtained a complete standard curve for a given motor, the test of a similar (or nearly similar) motor need only be carried far enough to obtain the tangent and, say, three points in the heating curve. The complete curves could then be surmised and drawn from the standard curve. By these means the behaviour of an enclosed motor under all ordinary circumstances could be demonstrated from a short test in a convincing manner and with sufficient accuracy for all practical purposes.

Mr. A. J. Cridge (Sheffield) thought it was not immediately obvious why the ratio mentioned should be the load factor. If the area of the current curve as taken on a recording ammeter were divided by the area of the rectangle representing the product of the maximum current and the total time, the ratio would correspond more nearly to what was generally called load factor. If Dr. Pohl had come to the conclusion that the two ratios were usually identical, he would ask the author to explain this. The curves and data asked for by Mr. Hartnell would, no doubt, be very interesting, but he (Mr. Cridge) rather approved of the way in which the author had reduced them to general equations, and with a little expansion they should be sufficiently practical for manufacturing purposes. He agreed with Dr. Pohl that the present practice in regard to the testing of motors for intermittent use was not satisfactory, and the institution ought to lay down some rules not only for this but for other testing work. This had been done in America. The rules were so frequently quoted that he felt British engineers ought to have something of the same sort. There seemed, however, to be a feeling that it would lower the dignity of this institution to deal with any particular subject; it must indulge in generalities. He did not think this attitude was helpful to the profession.

Mr. J. C. B. Ingleby thought it was not easy work to predetermine the rating of this class of motor. The method of circulating the air inside the motor had a great deal to do with the temperature rise in totally enclosed machines; for instance, taking a 20 H.P. motor with a one hour rating and a speed of 775 revs. per min., if this motor were rated for half an hour the speed could drop to about 510 revs. per min., or for a quarter hour rating to about 350 revs. per min. The temperature coefficients mentioned by the author would take quite a lot of finding, and even when found would probably soon have to be found again due to some drop in motor prices necessitating some slight change in the general design.

Mr. H. E. Yerbury (Sheffield Corporation Tramways Department) considered the subject matter of the Paper was important, but that it would be advisable to dissociate traction motors for tramways from such admittedly intermittent work as cranes, hoists and lift motors. Now that electric braking was being used to such a large extent in tramway work one could look upon motors for traction work as machines for short period working. The guiding principle enunciated by Dr. Pohl, as to the testing of any finished machine accurately representing its future working conditions, might be satisfactory from a designer's or manufacturer's standpoint, but he would go further and from a user's standpoint suggest that a machine should be subjected to continuous load above that for which it would be normally run. In the case of traction motors the usual period of test was four hours full load, but for crane and lift work a shorter test would be satisfactory, especially if it were at full load and continuous. Undoubtedly the heat-generating ability and heat dissipating quality of a motor were most important matters, and his experience of troublesome motors had been invariably traced to overheating and consequent failure of insulation. This applied to traction and other motors. He was pleased to hear that the author considered a very short time run unsuited even for intermittent running machines, and also that he favoured cast-steel yokes for motors. Some contractors preferred to use cast-iron yokes and did not like cast-steel yokes to be specified, presumably because they were not in a position to cast them in their own shops. He agreed with the author that there should be an established basis of rating and testing for all machines, but manufacturers should always be in a position to quote to an engineer's specification respecting, say, temperature rise for a certain machine working under exceptional conditions. Standardisation was good, but conditions of working often required specially designed machines.

Mr. W. T. Wardale believed the auxiliary motors on the battleships of our Navy were tested as intermittently working motors, and he thought that Dr. Pohl had brought forward a point in showing that for the first half-hour one got a misleading test: because in the case of motors working in connection with ammunition hoists on these ships, in the event of a long-fought action the temperature of the whole ship would go up tremendously, and, further, every shot which the ship received would, of course, strain to some extent the whole ship's framework, and it was quite possible the guides on which the hoists ran might be jammed. If these motors gave out at a critical time it would be a serious matter. With regard to designers running as near the wind as they dared by using cast-iron yokes, he thought in the long run they would reap what they deserved, because such motors would get classed as those that might stand the test on the test plate, but would not do the work outside. He suggested that the author should carry out tests in the following manner: Test in the ordinary way on the test plate with a set of motors for a crane, and afterwards equip a crane with these motors. If this was done under a full working day, a relation might be established between the practical working conditions and the test-plate conditions which might be valuable.

Dr. Pohl, in reply, said Mr. Hartnell had suggested that a series of tests should be carried out to ascertain exactly the heating and cooling curves of a number of motors, and that from such curves it would be possible to find out beforehand what the running conditions would reveal. The author had taken a number of such curves for direct-current and alternating-current machines, both of the totally enclosed and open type, but did not include them in the Paper because a fair amount of information had been published on these lines, and he thought he would be going to undue length by introducing a great deal of known matter. Curves of that kind were published, for instance, by Goldschmidt, to which reference was made in the Paper. The investigation of the working results by means of heating and cooling curves had been suggested by various authors referred to in the present Paper and, no doubt, reliable results could be obtained in that manner. If one knew the time constant at a certain speed it was possible to draw the whole of the heating curve, and if one knew the time constant for cooling one could draw the cooling curve. If one had then an intermittent load with any given load factor one might construct a curve almost exactly representing what obtained in practice. It was necessary, however, to know what the time constants were, and to find them by experiment. It was on this account that he thought such procedure was far too complicated to be adopted as a standard test for intermittently working motors. The time constant was a most complicated figure. His experience agreed with that of Mr. Hartnell, in that three-phase motors when totally enclosed showed more satisfactory results than direct-current machines. This was, perhaps, due to the cast-iron casing being in close contact with the stampings which were the seat of a great part of the losses, and also to the very small gap between stator and rotor that facilitated the rapid transfer of the heat from the interior to the surface. Mr. Cridge expressed some doubt as to the definition of load factor. The author put it forward as a suggestion and was inclined to think that it was largely a matter of choice what definition one adopted, so long as it was clearly understood what was meant. The reason he put it in the form $f=(\text{virtual current})^2/(\text{full load current})^2$ was, firstly, that by so doing the connection $f=(\text{mean loss under working})/(\text{loss at full load})$ was maintained, and, secondly, that it comprised as a special case the older definition $f=t'/(t'+t'')$. It was possible to test this latter point by a concrete example. These were two strong reasons for adopting the new definition. Mr. Hartnell had pointed out that it was not much good

Digitized by Google

putting a fan inside a totally-enclosed motor. This agreed entirely with the author's experience. At the same time, however, it would be wrong to deny that the circulation of air inside the casing had something to do with the heat dissipation of the armature. If a motor was run at an extremely low speed it was found that the temperature rise of the armature became very much greater than that of the enclosed air. He was much interested in Mr. Yerbury's remarks, but did not think it necessary to dissociate traction motors from crane motors. Heavier duty simply meant that the specified load factor for which they must be tested was correspondingly higher. He mentioned, as a concrete example, that some large railway motors which the Phœnix Dynamo Mfg. Co. recently supplied for most onerous duty on express passenger trains were, in accordance with the specification, designed and tested for unity load factor—*i.e.*, continuous running at full load. He could confirm what Mr. Wardale pointed out, that motors for ammunition hoists for the Navy were specified to be tested intermittently for a great length of time. This met Mr. Yerbury's point, that the heaviest possible duty which a motor might be called upon to perform was specified as the normal duty of the motor. He agreed with Mr. Yerbury that manufacturers should be capable of dealing with the requirements of buyers when specially designed machines were needed. At the same time, however, a large number of machines were special ones, and were in consequence more expensive, although they need not be special at all. This was due to the absence of rules on the rating and testing of machines backed up by the authority of the Institution of Electrical Engineers. He failed to see why the institution should not proceed to remedy this serious defect, which weakened English manufacturers in home and foreign markets in their competition with Continental and American rivals.

SOME APPLICATIONS OF THE "EOA" MOTOR.

In talking about electric motors the time has now come to leave the motor itself alone and to come to its applications. Every electrical engineer knows the motor so well and how it works that it

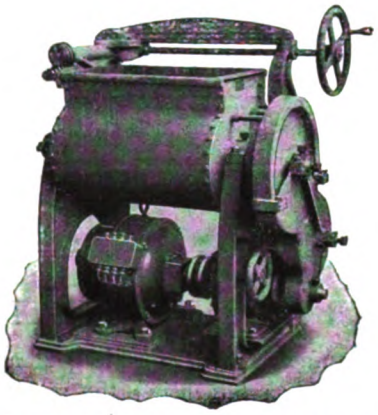


FIG. 1.—2 H.P. "EOA" MOTOR DRIVING DOUGH MIXING MACHINE.

would be more or less of an insult to attempt to teach him about these matters. But as regards the applications of the motor he is not, perhaps, so well-informed as he might be. Although he knows to a cer-

FIG. 2.—"EOA" VERTICAL MOTOR.

tain extent what a motor will do, he is not always very clear as regards particulars. These reflections are engendered by a glance through a booklet entitled "The Modern Method of Driving Machinery," recently issued by the Electric & Ordnance Accessories Co., in which are given some rather out of the way examples of what the electric motor can be and is being made to do.

It may be confidently anticipated that this pamphlet will do much towards inducing manufacturers in all branches of industry, who are at present "Philistines," to take up the employment in their works of the electric motor. The efficiency, simplicity, reliability, adaptability, and what may be called the other "ilities" of this machine are clearly, though concisely, argued out, the arguments being supported by financial details of the advantages derived by the employment of a motor as a substitute for the steam or gas engine.

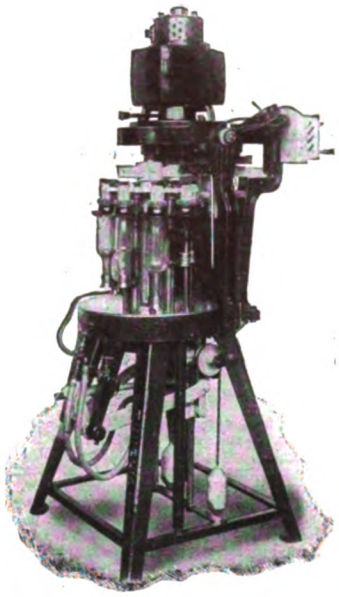

FIG. 3.—1 H.P. "EOA" VERTICAL MOTOR DRIVING BOTTLE-WASHING MACHINE.

In this connection attention may be called to the hire-purchase system devised by the firm with the idea of allowing manufacturers with small capital to obtain the benefits of the electric drive through easy payment arrangements. Under this system the Electric Ordnance & Accessories Co. are prepared to supply motors with the necessary controlling apparatus for a certain monthly or quarterly charge, the payments being spread over a period of one, two or three years, as may be desired. At the end of this time the motor becomes the sole property of the hirer. It should be noted that while the Company are always prepared to advise a customer on the best method of laying out his installation, they do not, save in exceptional cases, fit or erect the apparatus, but leave the work to the local contractor.

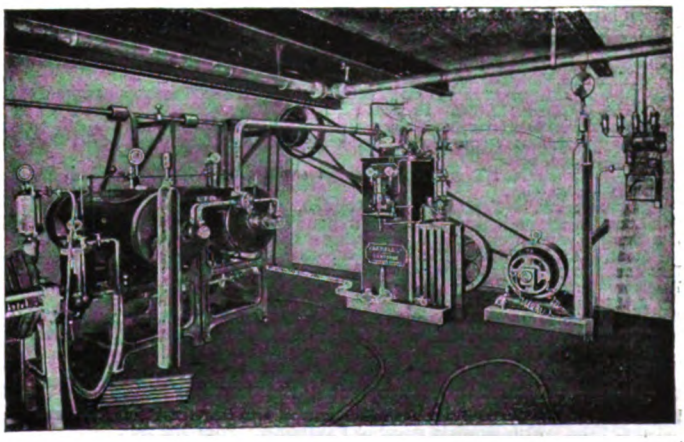

FIG. 4.—10 H.P. "EOA" MOTOR DRIVING REFRIGERATING PLANT.

The accompanying illustrations clearly show the general arrangement of some of the "EOA" installations and the uses to which the motors are put.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-seventh issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for April 1

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

Last week's number of "THE ELECTRICIAN" completed Vol. LXIV. With the April 22 number will be issued (Gratis) the Index to the Volume.

READY APRIL 29th.—Vol. LXIV. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXIV. are now ready, price 2s.: post free, 2s. 3d.

POWER SUPPLY EXTENSIONS.

Although manufacturers of electric generating plant in this country have been lamenting the small demand for new generators during the last few years, important developments have, nevertheless, been taking place in the electricity supply world, particularly in the case of the larger undertakings, in which the growing demand for electrical energy has necessitated during recent years the laying down of additional power stations. Our Annual Tables show that a considerable proportion of the large supply undertakings now possess at least two stations, and the number of undertakings possessing more than one station is increasing every year. Thus, within the past 12 months, we have described new power stations at Stepney and Dundee, and the names of other undertakings which have extended, or are extending, in this way will at once recur to the minds of our readers.

The question of laying down an additional station is one of the most important with which the central station engineer has to deal. In many cases the equipment and design of the original station probably leave much to be desired in the light of recent experience. Old stations usually contain a number of small units which were installed when the extent to which electricity supply would develop was not fully appreciated. In fact, there has always been a tendency when installing plant to underestimate considerably the requirements of even the near

Digitized by Google

future, so that extensions frequently became almost an annual procedure. This was, of course, to some extent unavoidable, as efforts were mainly directed to keeping down the capital expenditure of the undertaking, though this did not always result in a low cost per kilowatt of plant installed. As the smaller units become obsolete it is, of course, possible to remove them and instal larger plant, but this is at best only a temporary arrangement unless contemplated from the start, and the question of an entirely new station has eventually to be faced. This position is also brought about by the necessity of reducing the cost of generation to the lowest possible figure, so that electrical energy can be offered to manufacturers at a sufficiently low price to compete with private plants and with gas and other forms of light and power. In many cases the want of facilities for obtaining coal is such as seriously to handicap the undertaking, whilst to provide for efficient condensing may require an excessive outlay. Much has been written in regard to the various points to be considered in choosing a site for a power station, but with that question we are not for the moment concerned. It may be remarked, however, that in deciding to erect a new station it is frequently found desirable to modify the system of supply adopted. Thus, in the majority of cases where additional stations have been erected during the last few years three-phase alternating-current plant has been installed, notwithstanding that the existing system of distribution is continuous current or single phase alternating. A high-tension supply not only gives much greater freedom in the selection of a site, but is also particularly desirable where a large power load is being developed.

In this connection electrical engineers generally will take considerable interest in the forthcoming extensions of the Glasgow electricity undertaking, which is one of the largest and most important in this country. A report has been presented by Mr. W. W. LACKIE, city electrical engineer, in which he draws attention to the importance of making early provision for the probable demand for electrical energy in Glasgow, not only two years hence, but also during the next ten years. The existing stations at Port Dundas and St. Andrew's Cross are at present full of plant, and although the smaller units might be removed to make room for plant of larger capacity, Mr. LACKIE points out that at best this would only be a temporary expedient, and he therefore recommends the Committee to look out at once for a site upon which a new station may be erected. In coming to this conclusion Mr. LACKIE draws attention to the objections to extending the existing station at Port Dundas, viz. (1) the unsatisfactory supply of water for condensing purposes, the temperature of the canal water before entering the works being between 80° and 90°F., and (2) the high price which has to be paid for the delivery of coal at the works. In this connection it may be noted that coal at Port Dundas costs about 10d. per ton more than at St. Andrew's Cross, due to the former station possessing no railway siding accommodation. With the high load factors which electrical engineers are hoping for in the future, the cost of coal will become an increasingly important item, so that the facilities for obtaining coal cheaply are of almost first importance. In regard to suggestions for installing plant in the Pinkston power station of the Tramways Department, the same objection as to the use of the canal water applies, as this would involve heavy capital expenditure for condensing apparatus.

Mr. LACKIE sets forth the chief points to be kept in view in selecting a site for a power station as follows: (1) There should be suitable foundations for heavy machinery; (2) the site should be adjacent to a railway or canal, or otherwise situated so that a cheap supply of coal can be easily obtained; (3) there should be an ample supply of water at hand for condensing purposes; and (4) the site should be within a reasonable distance of the area to be supplied. It may be, of course, impossible to obtain a site with all these desirable attributes, in which case it is necessary to decide how far any, and also which, may be sacrificed. Mr. LACKIE comes to the conclusion that a site near Dalmarnock Road, with a frontage to the Clyde and adjacent to the Caledonian Railway, best meets the requirements, and possesses at least the two principal features desired, namely, the second and third mentioned above. As announced in our last issue the Electricity Committee have unanimously recommended the Council to approve generally of the report, and that the proposal to erect an additional generating station be further considered; meanwhile the ground is to be tested as regards its suitability for the erection of a large generating station, Mr. LACKIE having obtained an option on the land at 8s. per yard, the offer remaining open for acceptance until May 31st. The site also has the advantage that the new station could be easily and inexpensively connected up with the whole existing system.

In view of recent developments in America in the way of large generators, it will be of interest to see what size of plant will be installed in the new works. The latter certainly offers great possibilities in the way of economical generation of electricity, and in spite of the fact that the costs at Glasgow are already very low for an undertaking which has not the benefit of a traction load, there should be considerable reductions when the new plant gets to work. The question of a combined lighting and traction station will then probably again recur to the minds of electrical engineers, and the case for centralising the supply of electricity will undoubtedly be strengthened.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Electric Cables: Their Construction and Cost. By D. Coyle and F. J. O. Howe. (London: E. & F. N. Spon.) Pp. vi.+456. 15s. nett.

This book is mainly a collection of arithmetical tables, which the computer in the estimating office of a cable factory would calculate for his own special use, or, in other words, contains the "tools" which have accumulated in the authors' hands during their "(46 years in total) experience" gained at the various works mentioned on the title page, which experience they pit in the matter of the temperature coefficient for the electrical resistance of copper against (the how many years total?) experience embodied in the recommendation of the Engineering Standards Committee.

To continue the simile, these tools have not been fitted in all cases with suitable handles and have been heaped in with

Digitized by Google

lavish hand, but without adoption of definite system or sufficient explanation for the amateur, for without any intended disparagement the electrical engineer for whose use this book is intended may be so termed in this connection.

The metrical system is adopted to some extent, and prices are always given in shillings, no doubt as equivalent to the marks of the authors' continental experience, but tables exhibiting values per nautical mile, statute mile, 1,000 yds., &c., are added, just as fancy, or most likely factory, has determined, and with a minuteness of scale which is excessive; for example, 26 pages are covered with figures detailing the items for steel tape armouring of lead-covered cables for each $\frac{1}{10}$ mm. diameter from 10 mm. to 70 mm., and the want of system is illustrated by this same table, one column of which presents the "shop expenses" for each of the 601 sizes as a percentage on the wages and increasing by large steps at certain sizes from 25 per cent. to 75 per cent., but on referring to the sole brief paragraph on "shop expenses," we are told they "vary between 100 per cent. and 200 per cent." Even in the authors' hands these tools turn out curious results, for in detailed tables giving the prices of concentric cables, those for 2,200 volts working pressure are cheaper than for low pressure in all the larger sizes, and many such like things occur; while there is a general looseness in terms and weakness or even error in explanations of the formation of the tables that will require wariness and discretion on the part of the casual consultant of this book.

"The conductors are treated exhaustively" in the first 100 pages, but no reference is made to the B.O.T. sheath. Insulating materials are next considered, and incidentally we notice that some factories are stated to take liberties with "specific gravity," which term in this book often means anything but itself, and so the book proceeds at great length with the armouring and outside protection of the various types of cable, and closes with the description of the "grading of the insulation" of E.H.T. cables and the calculation of inductance and electrostatic capacity. The actual tests of the latter would have been more useful if the specific values of the insulation had been inserted in the diagrams.

In the section treating of telephone cables, a confusion arises in not distinguishing between "quad cores" and "quad pairs," while the dimensions calculated from the formulæ for the pre-determination of sizes for specified electrical values appear to give results far in excess of the demands of modern specifications.

Manufacturing wages are given mostly in the form of diagrams, which exhibit them, for various types of completed cable, as a variant with the size of the conductors, but far too much space is here devoted to jute insulation, which has been discarded for many years.

What with the standardising of E.L. cables, both here and on the Continent, what with the number and excellence of price lists and catalogues received by the electrical engineer, and what with the detailed specifications which the factories have to fulfil, and the obligations under which they have to work, we should hardly have expected that any "long-felt want" for a work of this genus existed; but, at any rate, a perusal of this book can only confirm the electrical engineer in his satisfactory contentment, if such he need, that the estimates in a cable factory, as elsewhere, are the result of a careful application of ordinary methods of arithmetical calculation. F. J.

Sammlung Elektrotechnischer Lehrhefte. By FRITZ HOPPE. Part II., "Grundgesetze der Wechselstromtheorie." Part VII., "Messungen der Stromstärke, Spannung, Leistung und Arbeit bei Gleich- und Wechselstrom, Eichung und Graduieren von Messinstrumenten." Part VIII., "Messungen an Maschinen und Motoren für Gleichstrom." (Leipsig: J. A. Barth.) Part II., pp. vi.+144. M.5. Part VII., pp. vi.+132. M.4.40. Part VIII., pp. vi.+168. M.5.80.

These three volumes form part of a series of booklets covering the elementary principles of electrical engineering. Each of the 10 sections in the series is made complete in itself in order that the student may buy separately such sections as he requires. The idea of bringing out these manuals in this form is a very good one, and the reviewer finds them the most suitable little handbooks for elementary students that he has come across recently.

The problems treated are handled in a practical way, and the writer is evidently an experienced teacher, as can be judged from the manner in which he expresses himself on points that usually present difficulties to the beginner. Great stress is laid on the discussion of actual test results and the working out of arithmetical examples, and, on the whole, one must admit that the writer has succeeded in his object, as expressed in the preface, of making the pupil "picture to himself clearly the phenomena that are described" and learn to "think electrically."

Part II. contains the general theory of alternating currents worked out with the aid of vector diagrams, and is concerned mainly with principles and only to a small extent with their application to alternating-current apparatus. It is somewhat confusing that one direction of rotation of the vectors is not used throughout the book, and although arrows are drawn in most of the figures to indicate the direction that is being used, yet it would be preferable to adopt one convention throughout.

The first item of importance taken is the determination of the winding factors for various types of alternator windings. These are not only tabulated, but a great number of cases are worked out fully. The effects of self-induction are then treated and the relations of the currents and voltages in circuits containing resistance, capacity and reactance in various connections.

In this part a serious error has been made in the calculations concerning an arc lamp controlled by a choking coil. The voltages across the lamp and the choking coil are added arithmetically instead of vectorially, and the power factor for the whole circuit is confused with that for the choking coil considered alone.

The student will get an exaggerated impression of the importance of losses in condensers from the fact that in nearly every case in which condensers are mentioned, they are represented as being equivalent to a capacity in series with a non-inductive resistance of such a magnitude that the voltage drops across the two parts are of the same order of magnitude.

After a very simple discussion of the regulation of an alternator at various loads and power factors the book concludes with vector diagrams relating to the working of transformers on various types of loads and some quite elementary remarks about polyphase systems.

The paragraph on p. 124 in which a proof is attempted of the fact that the approximate ratio of the currents in the primary and secondary windings of a transformer is inversely as the number of turns on these windings, is full of mistakes and should be re-written.

The following misprints appear in this volume:—Table on p. 84, *interchange* 40 and 60 and *read* 51 for 61; p. 90, Fig. 100, *read* 0·0306 henry for 0·036 henry; p. 96, last lines, *read* 0·62 for 0·643 and 0·785 for 0·766, and make the necessary changes that follow in consequence; p. 117, *read* W_i for W_2.

Part VII. treats of measurements with the voltameter, tangent galvanometer, electrometer, calorimeter and potentiometer, and of the use of most of the usual technical instruments and some useful hints on the method of calibrating and preparing scales for measuring instruments. The reviewer is of the opinion that the tangent galvanometer is treated at an unnecessary length, seeing that it has little more than a historic interest and is hardly ever used nowadays.

On p. 78, concerning the measurement of power by the wattmeter (not voltmeter, as stated in line 21), it should be stated that the deflection of the instrument is determined by the mean value of *the product of* the simultaneous instantaneous values of the currents in its two coils. (The words in italics are omitted in the text.) In the final equation on the same page containing the correcting factor for the reading of a wattmeter with self-induction in its shunt-circuit, the resistance of the shunt-circuit should appear in the numerator instead of in the denominator.

The measurement of polyphase power is well done, but there

Digitized by Google

are a few points that are open to criticism. The connection, as shown in Fig. 87, would be correct on a low-voltage system, but, as the full potential between two of the lines is bridged by the short air-gaps between the fixed and moving coils of the two wattmeters, both instruments would be liable to destruction by flashing-over if this connection were used on a high-tension circuit.

The connection for reading the power on a three-phase system by one wattmeter, as shown in Fig. 90, is wrong; it is there stated that a wattmeter connected with its current coil in one main and its potential coil between that main and one of the others will read $\frac{1}{\sqrt{3}}$ times the total power. A wattmeter so connected would read half the power on a balanced non-inductive load but in all other cases the total power could not be deduced from its reading alone. It is strange how prevalent this fallacy is. It should also be stated that the single wattmeter methods of measuring three-phase power, shown in Figs. 91 and 92, are only correct for balanced load.

Part VIII. is excellent throughout and will form a most useful aid to those who are engaged in the testing of continuous-current machines in the laboratory or in practice.

Each type of motor and generator is fully treated theoretically, and its characteristics thus determined checked by the results obtained by actual tests. Some of the theoretical formulæ have become somewhat complicated through the fact that Frölich's formula for the saturation curve has been used. It would perhaps be preferable in the interest of simplicity to refrain from attempting to express mathematically the somewhat complicated relation that exists between the flux and the number of ampere-turns on a machine.

A novel feature is the experimental investigation of the armature reaction of a continuous-current machine by a short-circuit test analogous to the tests commonly performed on alternators. The results obtained by this method are interesting, but in their discussion some confusion is caused by the printing of OD for OA near the foot of p. 39.

A. J. MAKOWER.

A PHYSIOLOGICAL EFFECT OF AN ALTERNATING MAGNETIC FIELD.*

BY SILVANUS P. THOMPSON, D.SC., F.R.S.

Hitherto it has been generally held that magnetism produces no physiological effect on any living organism, and although many persons have looked for such effects the results have been negative. Some years ago the author observed a faint visual effect when an alternating current magnet was placed near the forehead, and recently means have been found of producing the visual effect in a way that succeeds with every person upon whom it has yet been tried.

An alternating magnetic field of sufficient intensity and extent was produced by passing an alternating electric current around a specially constructed magnetising coil. This coil, consisting of 32 turns of stranded copper wire, having an equivalent cross-section of about 0·2 square in. in each turn, was wound upon a wooden cylinder about 9 in. in diameter, and about 8 in. long; the cylinder being then removed. The alternating current, of a frequency of 50 periods per second, could be increased up to 180 amperes at will; so that the total number of ampere-turns of the coil reached 5,760. The intensity of the alternating magnetic field at the centre of the coil had therefore a virtual value (quadratic mean) of about 1,000 C.G.S. units; and its instantaneous maximum value (at the centre of the coil) was therefore about 1,400 C.G.S. units. The value at the mouth of the coil was not much more than two-thirds of this amount, and was not uniform over the cross-section of the interior space.

On inserting the head into the interior of the coil in the dark, or with the eyes closed, there is perceived over the whole region of vision a faint flickering illumination, colourless or of a slightly bluish tint. The period of the flicker is not well defined. It does not seem to be the same over the whole region of vision at the same time, nor is it equally bright over the whole region of vision, but is somewhat brighter in the peripheral region than in the central parts. Even in daylight, with the eyes open, one is conscious of a sensation of flicker superposed upon the ordinary vision.

The effect is diminished by lowering the intensity of the field, and increased by raising it. Attempts to discover whether the brightness of the phenomenon stands in any relation to the direction of the axis of the field with respect to the directions of the principal axis of the scull have not yet revealed any definite result. It will be necessary to apply more intense fields than have yet been tried. No after-effects of any kind have been experienced, either by myself or by any of the persons who have made the experiments with me.

As yet it has not been possible to ascertain whether the phenomenon is dependent upon frequency. No effect upon the senses of smell or hearing has been observed, but there is an effect upon taste.

* Abstract of a Paper read before the Royal Society yesterday.

THE MOVEMENT TOWARDS A NATIONAL SYSTEM OF TECHNICAL EDUCATION.*

BY DR. R. POHL.

The problem of remedying the admitted inefficiency of our present methods of technical education, and of invigorating the industries of this country with progressive scientific spirit, while at the same time increasing the supply of skilled workmen, is of the greatest national importance, and is a problem the solution of which, in view of international industrial competition, becomes daily more pressing. It is only natural, therefore, that expressions of discontent with the present conditions, and suggestions for improvement, should be heard from many sides; they come not only from the educationists, but also from the employer, the representatives of the working classes, and the ratepayers, and with especial force from the social reformer; finally, we hear from Cabinet Ministers themselves, that legislation on the subject is under consideration. In view of this fact, it is most important that this Association of Technical Teachers should, at the coming Annual Conference, fully discuss this subject, and complete the constructive proposals laid down at the last Conference.

If we proceed to analyse the expressions of opinion, revealed during the last 12 months, there is a clear indication that, barely concealed under a superficial diversity of view point, the ideas have already crystallised round two fundamental principles which are certain to form the basis of all future constructive work. These are: (1) There should be a thoroughly organised system of technical education, leading up from the primary and secondary schools to the technical school, and having, as its crown, the technical university, every stage of the system being in intimate contact with the next, so far as possible without overlapping, and the educational work must be carried out in the closest possible co-operation with the employer. (2) This system should be a national one; that is to say, the Board of Education should not only inspect and supervise the individual institutions, but should ensure proper co-ordination; extend by law the leaving age for children, when and where necessary; enlist by all available means the co-operation of employers, and introduce a uniform system of examinations and degrees; and it should, from its exalted position, watch the working of the system, comparing it with that of other nations, and generally employing and developing the powerful weapon of technical education in the interests of the industries and the progress of the nation as a whole.

It has been stated that the proposals contained in my previous Paper were nothing more or less than a suggestion to adopt the Prussian system root and branch. I choose to deal with this entirely erroneous view, because it gives me an opportunity of showing what, to my mind, are the points of excellence and the faults, both in the Prussian and the average English systems. It will then be seen that by organically combining the good features of both, one can arrive at a system which, I believe, will meet the requirements of this country in a most efficient manner. I take it as being agreed upon that the scientific leaders of industry require much more complete training than the rank and file of the industrial army, chiefly the additional training of strict scientific accuracy, of research, and originality. That in view of the numbers to be dealt with in both sections, respectively, there must be a large number of schools for the rank and file in close contact with local industries, and a small number of colleges for the officers. This means decentralisation in the case of lower technical schools, and centralisation for the technical universities. How does Prussia attend to the needs of the rank and file? There were, in 1909, 23 national engineering schools, 24 national building schools, 7 national art and artisan schools, and 45 State-supported municipal technical schools of different kinds, including 6 textile schools, and 7 higher textile schools. Most of these institutions do no evening work, and the students pass through systematic courses extending over several years. During this time they are not in contact with practice, except that the building students, making the best of climatic con-

* Abstract of a Paper read before the Association of Teachers in Technical Institutions (West Yorkshire branch).

Digitized by Google

ditions, frequently work in summer and study during the winter months, and that other students sometimes do practical work during the summer vacations. Generally speaking, however, the students are not in contact with practice. I also incline to the view that there has been too much centralisation in this branch of technical education. As a consequence, there is a lack of intimate contact with local industries, and insufficient amalgamation of theory and practice. Furthermore, most of these schools do not really train skilled workmen and artisans, but what may be termed the non-commissioned officers of the industrial army. The courses are somewhat expensive, and, through the almost complete absence of a system of scholarships they cater more for the middle classes than the working classes. Another defect, and a very serious one in my opinion, is the absence of systematic co-operation between these schools and the technical universities, whereby students of exceptional ability would be sent up to the latter.

In England, the corresponding educational work is carried on in evening classes, whose most valuable and unique features are first and foremost, the intimate and continued contact of the students with practice, which infuses their daily work with heightened interest derived from the application of their studies, and which, on the other hand, reacts on the teacher and makes the courses, though they must remain theoretical, yet of a thoroughly practical nature and best suited to the needs of the local industries; and, secondly, the complete elimination of the bitter disappointment which many day students, in proud possession of first-class certificates and diplomas, now experience when they find that they cannot secure any suitable employment. This "Sandwich" or "half-time" system, which we so justly condemn when it is applied to primary education, is in my view, the ideal system for the training of the industrial rank and file. I am, therefore, of opinion that those who desire to see the present evening work abolished, and the day schools developed on the German lines, are very ill-advised. Whatever we do, let us retain the great feature of the English principle, that is, the concurrent training in factory and school. Let us make the present evening courses much more efficient by establishing proper co-operation with the employers, and by reducing the hours of labour, so that it becomes possible gradually to shift the centre of gravity from the evening to the day. Thus we shall obtain all we are striving for, without losing the great features I have emphasised, as well as the truly democratic spirit of the present system and its hold on the masses of the population.

I desire to offer one or two suggestions in connection with this important subject. We all agree it is not sufficient bringing pressure to bear on employers to give facilities for attendance at classes, but it is highly important, indeed it is essential, that we should secure their continued interest and willing assistance. There exists already a growing interest in evening classes. Let us do everything to enhance this sympathy, and convince employers that the developments which are shortly to take place are first and foremost in their own interests. But there is a further, and, if possible, more important point to be considered. The technical school, as thus firmly established by law, must not be an isolated unit in our educational system, but it must be a link in a complete chain. It must join at the bottom with the secondary school, especially with the technical secondary laid down as a desideratum in our resolutions of last year, and it should lead up to the technical university above. It is the need for an organic connection of the ordinary work with the highest form of technical education, on which I wish to lay particular stress. No better form can I imagine for this link than that of a comprehensive and national scheme of maintenance scholarships, by means of which the students of exceptional ability and enthusiasm are lifted up and trained to be the scientific leaders and original workers.

Thus we have arrived at the technical university, and, in passing, I will only remark that, up to this level of technical education, there is every likelihood of Prussia having shortly to learn a great deal from England. The aspect changes completely, however, when we contemplate the higher branches. In the latter, in Prussia, we find thorough organisation and efficiency, in England we find chaos and waste of energy and money. The explanation is simple: the Prussian technical high schools are national institutions, just sufficient in number for the needs of the whole nation so as to allow of intense specialisation in all branches. The many English institutions attempting higher technical work were founded by private persons, guilds, societies, municipalities, and whosoever liked to distinguish himself in this direction. The national government has made the sad mistake of generously supporting all these well-meant efforts, so far with little regard, apparently, to the effect of the one on the other. We must lose no time in remedying these defects before reaction becomes general, to the detriment of technical education and to the status of the technical teacher in particular. The borough, and even the county, is far too small a feeding area for a modern technical university, with its large staff of specialised experts in all branches, training original workers, carrying out industrial research and generally permeating the industries with progressive ideas.

As an introduction to a discussion on this question of the formation of these universities, one or two suggestions may perhaps be acceptable. Inquiries would have to be made to discover a ready means of correlating the work of universities with that of other institutions, which, as yet, is non-existent. Another important point to be settled is the number of technical universities needed, and their respective feeding areas. I believe that three for England and Wales, one for Scotland and one for Ireland, or even less, would be found to be sufficient for many years to come. And finally, the most difficult point as to the method of procedure will have to be decided. May I suggest, with the greatest deference, that in this connection the early and recent history of the Imperial College of Science and Technology may serve as a lesson how not to proceed. A further increase in the already excessive number of competitive institutions is clearly not wanted, but instead, a thorough amalgamation of the same and the replacement of mutually destructive competition by effective co-operation.

It is not unlikely that such amalgamation may soon be brought about so far as London is concerned, and an early extension of the principle to the provinces would then be within the range of probability. The leading institutions at present existing, in each university area decided upon, would form the constituent colleges; they might have the first and second years' courses in common, which, of necessity, would be generally scientific and educational in character, including such subjects as national economy, industrial history, industrial legislation, patent laws, &c., but the higher branches would be distributed according to the nature of the institutions and the industrial activities of the districts. Thus the desired concentration of effort and of students would be secured, and, by a process of natural development, the formation of a large staff of specialists in each branch working in intimate contact with their respective industries. In common justice, the old associates and graduates of the existing institutions should on application receive the corresponding degree of the new university into which their Alma Mater would be merged, a remark which applies more particularly to such historical seats of learning as the Royal College of Science, Royal School of Mines, City and Guilds Institute, &c., and to the leading provincial universities and colleges.

A scheme of more or less compulsory amalgamation as outlined above is, I know, distateful to many, and I am thinking more particularly of the remarks to that effect in Dr. Glazebrook's weighty and thoughtful Presidential Address to the Association of Technical Institutions. Yet I cannot bring myself to believe that there is the slightest hope of securing really efficient co-operation, and not merely a superficial affiliation, without some pressure from above. Needless to say, the amount of such pressure would be kept down to the lowest practicable minimum; to this end the detailed scheme of amalgamation, on the basis of certain guiding principles, might well be left to be settled by the institutions concerned, and no doubt the new universities, thus created, would be self-governing.

Higher technical education in England, if developed on such lines, would have adopted only one important point from the Prussian system, that is, organisation on a national basis, a point which, in my opinion, is indispensable to success. Other and less important points of similarity, such as the uniform system of examinations and of legally protected degrees, would come as a natural consequence. In more than one regard, of profound importance, however, the English would be far in advance of any existing system, so far as my knowledge goes; firstly, in its democratic principle, culminating in the character of its students, who, gathered by a process of sifting and selection, represent the genius of the rising generation in whatever sphere it may have been born—a class not of aristocratic idlers, but of enthusiastic workers. This ideal we shall approach only gradually, yet it is in sight, and we may accelerate its coming by advocating, that the fees of the new universities, for all except the scholarship students, shall not be kept low, but shall be at any rate in proportion to the cost of such institutions. The scholarship students will thus predominate more and more, which makes it possible at the same time to adjust the number of highly-trained men to the needs of the industries. We shall thus avoid excessive supply, which is a social and economic danger, and is a blame, often and not unjustly, attached to the German high schools. And finally, the close co-operation of the new universities with the respective industries would be a unique feature. It would be maintained not only, as in Germany, through the professors and lecturers, but through their advisory boards, and, what is perhaps most important, through the students themselves, who have been in contact with practice not merely for a short term of pupilage, like the average German student, but who have passed "through the mill."

STANDARDISATION OF ELECTRICAL MACHINES.

At a recent meeting of the Birmingham local section of the Institution of Electrical Engineers a paper was read by Mr. R. Orsettich on this subject, an abstract of the paper appearing in our issue of March 11th. The following is an abstract of the discussion which took place.

DISCUSSION.

Mr. M. Railing said that all manufacturers would agree on the advantages of standardisation. From the point of view of the public, standardisation was still more important. It aided cheap production by saving capital expenditure, ensured production being concentrated upon proved types rather than experimental types, and enabled existing stocks to be drawn upon in case of breakdown. He urged that more use should be made of the Institution rules. If these did not cover sufficient ground, attempts should be made to enlarge them. But only by the co-operation of the consumer, his advisory consulting engineer and the manufacturer in working to these rules could they arrive at complete standardisation. The question was one of national importance. Those who had to compete against large outputs of well-designed machines coming from the Continent and the United States could only hold their own by standardising as much as possible.

Mr. S. P. Smith (General Electric Co.) said that many points in connection with standardisation appealed to the designer, but particularly the question of relative cost of labour and material. A satisfactory solution could only be obtained by studying the total cost of the machines. Generally in electrical machinery the material was a more expensive item than the labour, and it would therefore seem that the designer would do well to cut the material as far as possible, at the same time allowing for better workmanship. Another important point related to the quality of the material, and on the whole it would be found that the best possible material was the cheapest. Closely connected with standardisation were the questions of ventilation and insulation. Most modern designs of machines were based on improved ventilation and consequently increased output. It might be thought a strange idea, but he believed that by the introduction of new insulating materials it would become possible to raise the heating limit in machines considerably, drawing the line at, say, 170 deg. rise instead of 70 deg. But it was quite true that such an insulating material had yet to come. He then referred to the lack of standardisation in the speed of direct-current machines. It made one wish that there was something corresponding to frequency that would fix the speed of direct-current machines. A difficulty in connection with standardisation was due to customers insisting so much on their own specifications. He suggested that it would be better to take the manufacturers' specification and work to that. There was always the safeguard of competition, and if the buyer could not get what he wanted from one maker he could get it from another.

Mr. N. B. Rosher thought considerable restraint had been shown in not attacking the great number of types of machines which had to be made nowadays. In the case of alternating-current machines there were no less than 16 different frequencies in use in this country. He agreed with the author that for alternating-current motors the best position for the slip-rings was outside the bearing. A slight disadvantage was that should it be required to take out the rotor it was necessary to remove the rings unless the bearings were split. The material of which rings were made were anything but standardised. Cast iron, cast or drawn copper, gunmetal and phosphor bronze were all being used. He would like the author's opinion as to the most suitable material. Another detail difficult to standardise was the arrangement of terminals. He preferred a cast terminal box which could be secured to a flat face on either side of the machine, and suggested flexible metallic tubing between the terminal box and the conduit. Mr. Smith had talked of 170 deg. as a possible future limit of temperature rise. He believed that the Admiralty were now allowing a temperature rise of this order in some machines which were being regularly supplied for special work.

Mr. A. E. Gott said the lecturer had laid stress upon the importance of stocking for orders. They would all like to do that, but it was only possible when everything was standardised. It was surprising the amount of money that was spent and sometimes wasted in little defects which greater standardisation would have prevented. In the examples mentioned he could not help thinking that the 1,000 and 2,000 revs. per min. speeds for the 1 H.P. machines were much too high; he did not know whether these were intended to be standardised or not. In regard to voltage, they could not have standard machines without standard voltages, and he was struck with the extraordinary number which prevailed in this country and on the Continent. He did not think that manufacturers paid sufficient attention to the details of electric motors, the terminals especially being frequently neglected by the designer. Nothing had been said in the Paper about split frames and split bearings which were absolutely necessary in certain cases. As to reduction gearing, he entirely disagreed with the practice of putting the gear on top of the motor. The case was never designed to stand the strain, and was consequently liable to be broken. He thought that in standardisation allowance ought to be made for fitting flywheels to the motor shafts.

Mr. A. E. Anderson thought that by keeping one's workmen constantly employed on the same line of work there was a danger of making machines of the men. The same thing applied to the standardisation of designs. It was a very fair question to ask whether that did not tend to stultifying invention. It seemed a fair argument that with three or four different varieties of work they would reach a much higher point of efficiency and economy of material. Dealing with the question of general standardisation and diameter of core, he did not agree with the author's statement that for continuous-current machines it was advisable to have a separate diameter for every length. Personally he thought they ought to have at least two lengths to get the requisite degree of flexibility, because it was a very difficult matter to standardise armature windings. The same would also apply to the author's statement that the stampings of continuous-current machines should be arranged for one or at the maximum two numbers of slots only.

Mr. A. Willmott said that the Paper rather appeared to miss the initial start of standardisation. What was wanted to start with were correct drawings. Also there was no mention made of the question of inspection. This was a very important point in standardisation and shop production. If they did not want to waste money they must have good men who could be relied upon to see that when machines were going through the shop there should not occur trivial defects, to be discovered afterwards on testing. The Paper only mentioned cast iron for the yokes, but they could now get a very good quality of steel casting which could be obtained at a fair competitive price. The delivery might be quicker with cast iron, but with standardisation this was not of such great importance. With regard to brushholders he thought it was better to increase the number of carbon blocks than to increase their thickness.

Mr. Holt said, with regard to the possibility of standardisation stultifying progress, he thought one of the reasons why it had not been carried to such an extent in electrical machinery as in some other things was that the electrical machine so far had not reached finality. They must not begin to consider the question of standardisation until they had standard requirements, and in that matter their Institution must play a large and important part. With regard to field coils, where these were standardised at 220 volts he found that when used on 230-volt circuits where the regulation was bad they were liable to overheating and breakdown. It seemed best to design standard machines for ordinary standard voltages and to treat any departure from these as a case for a special machine. As regards patterns, his experience was that wooden ones had a very short life, and that iron ones, except in very small sizes, were too cumbersome. He thought that the outlay on patterns should be kept as small as possible. As to the use of enamelled wire, he had found it satisfactory in field coils where it could be wound in regular layers, but it was quite useless in armatures where it was subjected to a great deal of twisting and handling and where wires crossed one another at the coil ends. He had had a number of ball bearings running quite satisfactorily, and believed that in many cases their failure was due to faulty mounting.

Mr. Orsettich, in reply, said that Mr. Smith perhaps did not mean to be so radical as he seemed to be. He probably meant to say that the specifications of consulting engineers should lay down the principal lines of the specifications, stating their requirements, but should not insist on small details of construction. If this was what Mr. Smith meant they were perfectly in agreement, and he believed every consulting engineer would be of the same opinion. With regard to Mr. Rosher's remarks concerning the large number of machines proposed as a basis of standardisation, this was an essential condition of its acceptance. If the number of standard machines was not sufficiently large there would be occasion for special machines to be made. The material used for slip-rings was not of great importance, especially where short-circuiting gear was fitted to the motor. Phosphor bronze, steel and malleable iron had all been employed. Malleable iron was more satisfactory than steel for shrinking purposes. Phosphor bronze answered equally well, but it was more expensive and less durable. The brushes in standard machines should be of carbon only, but in certain cases with low voltages made-up carbons with copper plugs inserted could be employed. Copper brushes could be used with slip-rings, especially if the latter were of malleable iron. As regards ball bearings, his own experience had been that the balls sometimes broke, and the broken pieces damaged the shaft badly before they were found out and removed. If it were possible to come to an agreement as to the position of terminals manufacturers would be very glad to comply with clients' requirements. He was afraid that the Home Office regulations would hardly regard a tube clamp on the terminal board as an effective earthing device, a definite section of copper would have to be allowed. He agreed with Mr. Gott that the speed of machines should be kept as low as possible, but there was a large market for high-speed machines. The general practice with regard to split frames was that where the armature became too heavy to be lifted out by two men it was necessary to split the frame. This happened at a diameter of about 14 in. In reply to Mr. Anderson, he was not afraid that the adoption of strict standards would lead to a crystallising of types and stopping of progress. As regards the use of two or three lengths of core, from the point of view of the cost of dies, he did not know whether speakers had in their minds the idea of combination dies. The question of cost was not so serious if they had blank dies, when one die could be used for two or three sizes. As to drawings and inspection, he had pointed out at the beginning of his Paper that he was not dealing with the question from the shop point of view. He was afraid that Mr. Willmott's suggestion of altering the number of brushes instead of their thickness was hardly practicable, because it meant increasing the length of the commutator every time the current was increased. As regards the question of armature stampings, he believed that when the diameter of the centre piece saved by the use of a spider was 10 in. or less the saving was not sufficient to warrant the use of the spider. A heavy machine with ball bearings had been mentioned in the discussion, but he believed that roller bearings had been substituted in that machine about six months ago.

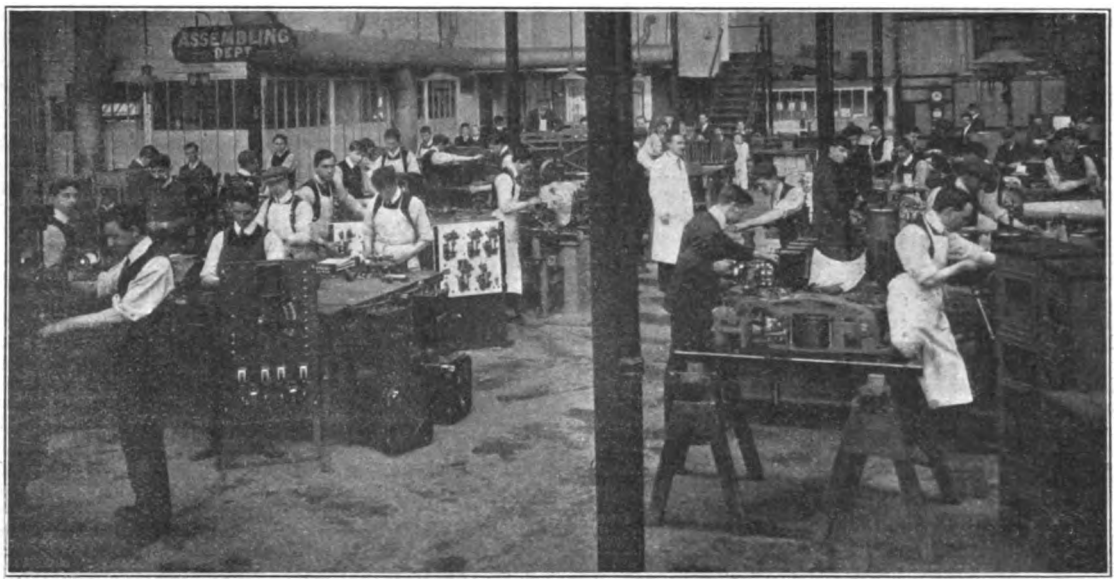
"IGRANIC" ELECTRIC CONTROL APPARATUS.

A VISIT TO THE BEDFORD WORKS OF THE ADAMS MFG. CO.

On Friday last, at the invitation of the Adams Mfg. Co., a party of technical journalists travelled down to Bedford and were given an opportunity of inspecting the latest types of Igranic electrical control gear, and also the works from which the specialities of the Adams Mfg. Co. emanate. The party were entertained at luncheon by Mr. A. H. Adams and the officials of the Company, and immediately following an excellent repast a large number of lantern slides depicting the principal Igranic standard gears were thrown on the screen. Mr. Adams briefly emphasised the importance of standardisation in motor control gear, and explained that it was the object of his Company to specialise in this branch of manufacture with a view to the production of the most efficient forms of apparatus for controlling motors of every size and type. He pointed out that considerable difficulties had been experienced in bringing about a satisfactory standardisation of apparatus owing to the variety of types, but that by a close study of the results of experience it had become possible to put forward a regular range of control gear which could be relied upon in every respect. We have from time to time directed attention to the many improvements which the Adams Co. has introduced into its Igranic apparatus; consequently, it is not necessary for us to go into the special details of design and construction which distinguish this form of motor control gear. The details of the various slides were explained by Mr. J. T. Mould, and many interesting types were depicted. Among these were three large Igranic gears installed in the works of Messrs. Cammell, Laird & Co. for the control of three overhead cranes which handle hot steel ingots. Each of these gears controls some 350 H.P. of motors, and the whole of the operations are performed on a drum type master controller which is connected to the circuits of solenoid operated contactor switches fixed at some distance from the operator. Other slides showed examples of Igranic apparatus in use in American steel works and rolling mills, one of the most interesting of these being a gear which controls a motor hoisting a hot bloom weighing some 60 tons, the whole of the operations of starting, accelerating and stopping the motor occupying a space of only 2½ seconds. Examples of printing press controllers were also thrown on the screen, and Mr. Mould laid special emphasis on the fact that the Igranic gear has overcome the difficulties attendant upon the "inching" of heavy flat bed and newspaper printing presses. We have described this form of gear in the columns of THE ELECTRICIAN (Vol. LVIII., p. 929). Probably the most interesting slide was that showing a novel application of the lifting electromagnet. As our readers are probably aware, this crane accessory has been brought to a high pitch of perfection by American electrical engineers. We understand that the Adams Co. is acting in this country for the Cutler-Hammer Co. for the sale of



IGRANIC WORKS, BEDFORD. A CORNER OF THE ASSEMBLING SHOP.

IGRANIC WORKS, BEDFORD. A PORTION OF THE RHEOSTAT GALLERY.

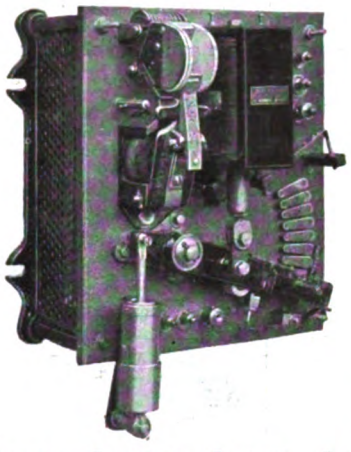
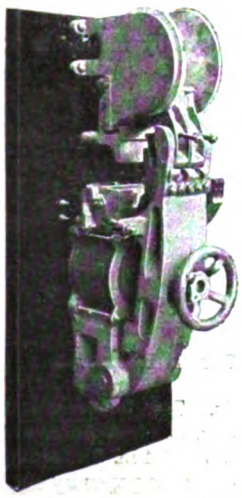
the latest form of these lifting magnets. The slide in question depicted one of these magnets raising from the bed of the river Mississippi a portion of a cargo of nails which had fallen through the bottom of a barge and had slipped from the bank into the bed of the river. We were informed that the whole of the cargo was recovered in this novel manner, and the Company is of the opinion that there is a considerable future for the lifting electromagnet in salvage operations. The difficulty which has previously been experienced is the keeping of the magnet winding quite dry, moisture usually finding its way in and breaking down the insulation. The illustration of this novel incident, which we are able to reproduce, had only arrived from America on Friday morning, so that the Company must be complimented on its enterprise in showing it to the party present.

LATEST FORM OF STEP-BY-STEP STARTING SWITCH WITH NO VOLT AND OVERLOAD RELEASE.



IGRANIC SOLENOID STARTER COMBINED WITH "CLAPPER" TYPE CIRCUIT BREAKER AND NO VOLT RELEASE.

After luncheon the party adjourned to the Company's works, which occupy a site of some 6 or 7 acres lying in an angle formed by the intersection of the Midland and London & North-Western Railways. Arrangements had been made to conduct the guests over the works in parties, and the various stages of the manufacture of Igranic rheostats and control gear were explained and demonstrated seriatim. The electrical works have a floor space of some 22,000 sq. ft., and adjoin the automobile works, which are responsible for the production of the well-known Adams cars. The layout of the shops into departments has been carefully arranged so as to facilitate the passage of the raw material from the preliminary to the final processes with a minimum amount of delay and re-handling. The equipment of the testing department is complete in every way, and the party was given an opportunity of witnessing the operation of several new forms of control gear under actual service conditions.



IGRANIC CLAPPER TYPE CIRCUIT BREAKER MADE IN CAPACITIES FROM 5 TO 10,000 AMPS.

IGRANIC DISTANT STOP PUSH BUTTON WHICH OPERATES IRRESPECTIVE OF LENGTH OF LEADS.

As to Igranic apparatus, as we have already mentioned, the main features of this will be well known to our readers. We are, however, able to give illustrations of one or two of the Company's most recent productions, to which more than ordinary interest attaches. Special attention has been paid to the design of clapper and contactor type remote control switches, and these are now made in small size for direct attachment to Igranic starters, and in larger sizes for independent operation as circuit-breakers. We were shown in the testing room an example of one of these clapper switches having a capacity of 8,000 amperes 600 volts. The carbon and magnetic blowouts have been carefully designed, and every precaution has been taken to protect the costly laminated copper bridge pieces from damage which might arise if any arcing took place at this point. A decided novelty which was also shown is a distant-stop push button for short-circuiting the no-volt release coil of motor starters from some distant point. The ordinary arrangement does not make any allowance for the length of the push button leads; consequently, if these are unduly long, their resistance is sufficiently great to render the device inoperative. With the latest Adams device this difficulty has been overcome, and the push button can be placed at any distance from the starter. It can, of course, be utilised in conjunction with any ordinary starter without alteration. Another new form of Igranic gear is a combined auto-starter and main switch. The starter is solenoid operated and is upon standard Igranic lines. Immediately adjacent to the solenoid is a small clapper type electrically-operated circuit-breaker, which makes and breaks the main circuit. A combination of this type makes the whole apparatus much more compact and reduces erection expenses as well as the cost of the gear. Another interesting switch of recent introduction is that known as the "straight line multiple starter." This is one of the neatest step-by-step starting switches which has come under our notice for some time. The apparatus consists of a number of superimposed switches which are so connected to the operating handle

IGRANIC LIFTING MAGNET RAISING PORTION OF A CARGO OF NAILS.

that the oscillation of the latter brings each switch consecutively into circuit. The bottom switch, which is the first to close, is held in by a no-volt release magnet, and is provided with a carbon break and magnetic blowout. The other switches are automatically released after the fall of this bottom switch. If desired, an overload circuit-breaker interlocked with the first switch can be fitted to protect the motor against heavy starting currents. The device can be oil immersed or enclosed in dust-proof and watertight cover. An arrangement can also be made for speed regulation if necessary.

The visit to the Igranic works was pregnant with interest at almost every turn, and we found the time all too short in which to make closer examination of the Company's many interesting products. Nevertheless, abundant evidence was forthcoming that the strictest attention is paid to the minor as well as the important details of motor control gear, and it is doubtless upon this account that Igranic gear enjoys its present well-deserved reputation.

BOOKS RECEIVED.

(Copies of the undermentioned works can be had from *The Electrician* office, postfree on receipt of published price, adding 3d. for books published under 2s., and 5 per cent, for books published nett. Add 10 per cent. for abroad or for foreign books.)

FROSTING, ETCHING AND COLOURING INCANDESCENT LAMP BULBS.*

The Lamp Committee of the National Electric Light Association have prepared the following information on the subject of frosting, etching and colouring incandescent lamp bulbs :—

Frosting Lamps.—Frosted lamps improve lighting results by giving better diffusion and more agreeable lighting. A properly frosted bulb cuts off comparatively little light, averaging from 3 per cent. to 7 per cent. The useful life of frosted lamps is about 60 per cent. of that given by corresponding clear-bulb lamps, but the breaking life is practically the same for both clear and frosted lamps.

Lamp bulbs may be superficially frosted by dipping in a compound which can be purchased from various manufacturers ; this frosting is not permanent, however, nor as satisfactory as the etched frost given to the lamps by the manufacturers, which is effected either by sand blast or by acid. Both processes give very similar results, but for incandescent lamps the acid method is generally used. This employs a solution consisting of hydrofluoric acid and carbonate of ammonia thoroughly mixed in a proportion of about 10 qt. of acid to 8 lb. of ammonia. Where it is required to frost only a portion of the lamp, rubber hoods are placed over the lamps to a point where the frosting is to stop. The acid operation is dangerous and requires considerable experience in order to obtain successful results. The work should be done in a specially ventilated room, and the operator should be thoroughly protected by rubber gloves and apron.

Frosted lamps may be cleaned by dipping them in very hot water and rubbing them thoroughly dry with tissue paper. Where this is not sufficient, a little soap should be used with the hot water. Tungsten lamps should always be burning while being cleaned.

Etching on Lamps.—The acid etching of letters or symbols on lamps is not attended with the objections and difficulties of the complete frosting process, and can be readily employed by any company to mark its lamps permanently. It is suggested to the smaller companies that should they meet with difficulty or loss in the theft of lamps, a method of identification should be adopted. The formula suggested for making an etching fluid is as follows : To 1 lb. of ammonium fluoride crystals add 1 oz. of 52 per cent. hydrofluoric acid and 8 oz. of water. Stir this solution occasionally and let it stand over night, when it should be strained. Then strain the clear part of the solution through medium coarse muslin. Care should be taken in the selection of the ammonium fluoride crystals, which should be of fairly large size. Sheet lead or hard rubber vessels should be used as containers for the etching fluid.

Colouring Lamps.—Lamps of which the glass is permanently coloured are the only ones that are thoroughly weatherproof. As such lamps are rather expensive, superficially coloured or dipped lamps are quite generally employed. Old or dim lamps removed from the circuits may be used. The most desirable colours for lamps are opal, yellow and ruby. A very satisfactory opal dipping is available and can be employed in preference to frosting in many cases, as the dipping gives a smooth finish and the surface of the bulb is not so liable to collect dirt and get black, as in the case of the frosted bulb. Blue, green and purple are not desirable, as these colours absorb so much of the light that the lamps are hardly distinguishable at a distance.

THE RAYMOND-BARKER SYSTEM OF CABLE INDUCTIVE SIGNALLING.

During the making of the final splice of a recent repair by c.s. " Buccaneer " on one of the Atlantic cables (core mainly 450 Cu/|| 270 G.P.), very satisfactory working—involving rapid exchange of many actual messages, also questions from London and replies thereto concerning the operations of steam-trawlers—was carried on through the medium of the above system.

In order to test practically the more complex conditions accompanying the closing over of the sheathing wires in the making of an overlapping splice, the exchange of messages was purposely deferred until after the completion of the final joint, during the making of which inductive working—as frequently proved—encounters absolutely no difficulty.

The cable distance covered by the inductive signalling was—ship to shore—66·6 nautical miles. On the cable in question 100 miles would have been equally easy. One Gott fault-searcher coil of Silvertown make was attached outside the cable. To quote competent authorities ashore and afloat, two-tone signals sounded " as clear as a bell." Signals could have been made louder by the application of two or more Gott coils in series.

The " Buccaneer " is fitted with " wireless," and is well-known to the radio stations. Clearly, however, the two-tone vibratory inductive system, which keeps " ship " and " shore " in close signalling touch almost up to the moment of slipping the final bight, must be possessed of inherent advantages which do not attach to the present radio system, unless, indeed, the cable station is itself fitted with " wireless," a circumstance not frequently met with.

* Abstract from the " Electrical World."

AUTOMATIC COURSE RECORDER.

At the exhibition of apparatus last December by the Physical Society of London Messrs. C. F. Casella & Co. showed a new automatic safety course recorder, brief particulars of this instrument being given in our issue of January 7, 1910. The apparatus is intended for recording and indicating the fact of a vessel deviating from

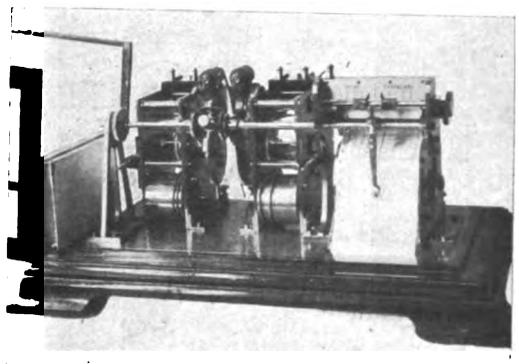

Fig. 1.—Course Recorder and Indicator.

the true set course, and for ringing an alarm bell when such deviation exceeds a certain prearranged limit. The value of such apparatus has long been recognised by navigators, but it has not come into extensive use, probably partly owing to certain objections which have been raised against existing apparatus. One of the principal difficulties in designing such devices is the extremely small directive power of the magnetic needle itself, so that the introduction of any electrical contacts is liable to cause trouble. An attempt to surmount this objection has been made in the Hennah and Rissel course recorder. In this apparatus no contact is made by the compass needle or card, but instead a variation of electrical resistance is caused of an amount corresponding to the amount of deviation of the vessel from the true set course. The change in the current flowing in two electric circuits brought about by this variation in resistance affects the speed of two differentially-geared clockwork mechanisms by means of electro-

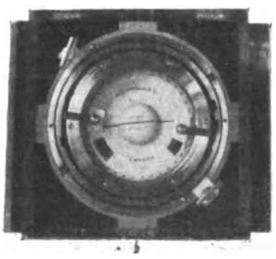

Fig. 2.—Compass used with Course Recorder.

magnets acting on the clock movements. The recorder and indicator consists primarily of a band of paper, which is made to travel by means of clockwork at a constant rate, about 4 in. per hour, and of a pen capable of being moved laterally across the paper by the difference in speed of the two differentially-geared clockwork mechanisms. So long as the vessel is on her true course and the recorder and indicator put in action by the compass being set to the proper course, both clocks will receive the same amount of current in their controlling electromagnets, and no motion of the stylus or pen will result. Should the vessel deviate from this course, however, one clock will be retarded and the other accelerated, thus causing through the differential gearing a motion of the pen in the required direction, recording the fact of the vessel's deviation, the angle of such deviation from the true set course and the period of time thereof. Two alarm contacts are placed above the stylus arm, and are capable of

Digitized by Google

being set to the required alarm period by means of a right and left-handed screw. A divided scale coinciding with divisions on the paper band is also provided, facilitating the setting of the alarm period.

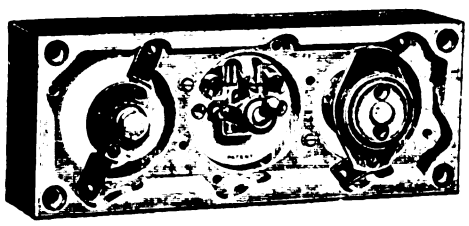
The compass is undoubtedly the most interesting feature of the apparatus. The card is composed of mica and has two slots cut in it, whilst the compass contains a solution of copper sulphate. Two pairs of electrodes, one pair for each electrical circuit, are employed, one electrode in each case being placed above and one below the card. It will be evident that the movement of the card relatively to the electrodes will affect the resistance of the circuit between each pair of electrodes, due to the position of the slot. The electrodes are arranged so that the reduction in resistance of one circuit due to the slot approaching one pair of electrodes is accompanied by an increase in the resistance of the other circuit. Current is provided by an accumulator, and when the compass is set to the desired course this results in the resistances of the two circuits being equalised, and consequently in equal currents flowing in the windings of the electromagnets affecting the clock mechanisms. It may be mentioned that the total current taken from the accumulator does not exceed about 90 milli-amperes.

Fig. 1 shows the course recorder and indicator, whilst Fig. 2 gives a view of the compass. The apparatus is being placed on the market by Messrs. Sharland & Co., of Eldon-street House, London, E.C., and is likely to arouse considerable interest in the marine world.

ADAPTABLE "SWITCH COMBINATION."

Messrs. A. P. Lundberg & Sons' ingenuity in the way of designing switches to do all sorts of wonderful things, to turn lights on and off from several points, and generally to cater for the present day lazy human being are well known. It is scarcely, therefore, surprising to find them turning their ideas to another matter, and attempting to introduce standardisation and uniformity into switch grouping.

They inform us that owing to a want of uniformity in the methods adopted, and the absence of articles standardised for the purpose, the satisfactory grouping of switches and kindred accessories together often becomes an awkward and expensive problem for the wiring



"Adaptable Combination" with the Front Removed.

contractor, and hap-hazard methods have often to be employed to meet special cases. To avoid these undesirable conditions they have, therefore, designed the "Adaptable Combination" shown herewith, which consists of a block of glazed porcelain arranged with three suitable recesses to take the Lundberg standard types of switches, wall connections and bell pushes. The need of such standardisation has, Messrs. Lundberg think, become more acute since special tariffs and cheaper and more reliable apparatus have made electric heating and cooking more popular. The combined bell and telephone systems, now so universally employed, also need to be properly installed, and grouping with other accessories is often found a convenience. On modern installations on board passenger ships the various accessories for controlling the lighting, heating, ventilating, telephone and call-bell arrangements are also conveniently grouped together.

The "Adaptable Combination" can be fixed either horizontally or vertically and with either surface and ordinary cover plates. The illustration herewith shows, as an example, the combination arranged for the horizontal fixing of a "Pixy" bell push, "Pivot" single-way switch and "Universal" wall connection. Metal straps of suitable shapes have been standardised, and these support the various accessories in a substantial manner, the fronts being screwed on in the usual way by threaded rings or by providing fixing screws for the block with tapped holes. The neatest effect is then obtainable, as no fixing rings are required on the accessories.

The "Adaptable Combination" is capable of accommodating any of the various types of Lundberg standard switches, wall connections (two and three pin) or bell pushes arranged in any desired manner. Additional contacts in connection with an electric bell system, or combined bell and telephone system, can also be simply arranged at small extra cost. Should circumstances require such, two single-way switches may be coupled by a bar in the usual way, and connected in parallel, and so control a wall connection of 10 amperes capacity fitted at the third hole, supplying current—*e.g.*, to a radiator. Two single-way switches may be similarly coupled by a bar and connected to form a double-pole switch.

RADCLIFFE (LANCS.) POWER SUPPLY.

A Board of Trade inquiry, which extended over five days, was held last week into the refusal of Radcliffe Council to allow the Lancashire Electric Power Co. to supply electricity in their district.

Mr. C. H. Pickstone, for the company, said the inquiry was being held because Radcliffe Council, who were the authorised distributors of electricity under a provisional order of 1895, had refused to consent to the application of the company for permission to supply current in Radcliffe, with the result that the Board of Trade had been requested by the company to dispense with that consent, and the Board of Trade, in order to satisfy themselves as to whether they ought or ought not to dispense with Radcliffe's consent, had sent an Inspector (Mr. A. Read) to inquire into the circumstances. Mr. Pickstone then gave particulars of the powers of the company. In 1904, he said, they got sanction to take transfers of the electrical undertakings of local authorities, and had taken a considerable number of transfers with the sanction of the Board of Trade. Parliament in 1906 gave them largely increased powers. The company was relieved of certain fetters and authorised to supply persons with power within their area, but there was a condition that the company should not supply energy in any area which formed a part of the area of supply of any authorised distributors without the consent in writing of those distributors. The Radcliffe Council were the authorised distributors within the area of their township, so that the company found themselves precluded from dealing with anyone in Radcliffe without their consent in writing. The company alleged that owing to the way the Council had dealt with the applications from the company the latter had found itself so fettered not only in regard to its own development, but in reference to the demands of the ratepayers of the town that they felt bound to go to Parliament for a provisional order so that they could supply in Radcliffe without the consent of Radcliffe Council.

The Inspector: Do you say that apart from any question of the particular way the Council have dealt with applications in the past it is desirable your powers should be extended and the Council's consent dispensed with?

Mr. Pickstone: Undoubtedly. The main issue is as to whether it is to the interests of Radcliffe that power users shall be able to freely treat with the company or get their supply through the Council. He contended that in granting Radcliffe its provisional order Parliament had not conferred upon it a monopoly that could not be given to anyone else. The company said that under their powers and under their application they were still in the same position as any other company who sought for a provisional order. Apart from clause 5 of their special Act they should be in a position to go to the Board of Trade for that provisional order, and the probabilities were there would have been no inquiry necessary; and he suggested that the Board of Trade desired to know before they dispensed with the consent of Radcliffe Council what were the circumstances of the case. In their request for the provisional order to dispense with that consent the company contended there was a large demand for electrical energy in Radcliffe, and that the Council were totally unable to meet that demand. Mr. Pickstone then quoted at great length from the correspondence which had passed between the parties, and cited certain applications to the company for a supply of electricity for power.

Mr. John W. Kenworthy chief engineer of the Bleachers' Association, said the association had two works in that district. His firm was one of those who attached their signature to the petition sent to the Board of Trade in support of the application, because they wanted power to Whittaker's at Mount Sion. They installed, in agreement with the company, a motor. They were particularly satisfied with the conditions and the general running received from that source, and ultimately decided upon making another extension of about 150 H.P. with the Lancashire Electric Power Co., so that they had now approximately 500 H.P. They would have liked to instal an extensive plant at Andrew Greenhalgh's. They approached the company, but the company said that under the present arrangements with Radcliffe Council they were not able to give a supply. Therefore, they put down their own plant at an expenditure of £800. They would naturally like to deal direct with the company they were going to deal with. If they wanted to deal with that question they wanted to deal with it promptly. Sometimes they wanted 200 H.P. or 300 H.P. very urgently. They would not be particular whether the supply was by the Council or the company so long as they got the same terms. They ought to be able to choose for themselves. The liberty of trading freely with consumers wanting power would be beneficial to the district.

By Mr. Keen (for the Council): They were not dissatisfied with the supply obtained for Mount Sion Works. He desired the company to obtain the provisional order so that the consumer could deal with the company direct.

Mr. S. Walker, ironfounder, said that his firm had signed the petition in favour of the company's application because the Council ought to

Digitized by Google

afford the ratepayers every facility for getting the cheapest and best article to enable them to carry on their business and develop their trade. As the Council could not supply large quantities of electricity themselves, he believed in the company coming in It was very essential that Radcliffe, more than other places, should have cheap electricity, as the town was handicapped by dear water and dear gas. He was conducting a business outside Radcliffe which could not possibly succeed in Radcliffe owing to the high prices of gas and electricity. A cheap electrical supply would be the saviour of the town. If the company and the Council worked together he believed it would be an all-round advantage.

Mr. JAMES MARSH, Manager of the Black Lane Spinning Co., said there was delay when his firm wanted a large supply of electricity from the company, and negotiations had to proceed with the Council. Large firms ought to deal direct with the company. His firm alone could absorb the whole of the power from the Radcliffe Council's generating station straight away.

Mr. C. R. SEDDON, managing director of the East Lancashire Paper Mill Co., said his company's works were rated at nearly £3,000 a year. They had their own plant for generating electricity. They did at one time desire current from the company, and they made application in Feb., 1908, for power. They could have come to terms with the company, but they did not want the terms to be known to others. The Council could not give them either the power they wanted or the emergency power then desired. The matter went off with the company because his company would not negotiate through the Council. They must have bulk power at a low rate, and only the company would be able to give it them and give them an advantage they could never expect from the Council. They took a little supply from the Council for week ends which came to about £50 a year. For the bulk of the power it would be advisable for paper works to put their own plant in for electric power, but his company had no intention of considering it from that point of view. So long as he could get power at a remunerative price, he did not care whether it came from the company or the Council.

Mr. J. H. BLAKEY, smallware manufacturer, said that as the result of a fire at his mill a supply of electricity was required, and he made temporary arrangements with the Council. He found, however, that the Council's price for electricity was too heavy, although, considering the amount he was taking, he would not say it was an unreasonable price.

Other local manufacturers and traders having given evidence,

Mr. FRANCIS E. GRIPPER, director of the company, gave evidence of the financial position of the company, &c. He said he was interested in 40 or 50 distribution undertakings working under provisional orders, and in his experience it was quite impossible for any of those undertakings —some of which were smaller and some much larger than the Radcliffe undertaking—it was quite impossible in such stations to attempt to supply anything or anyone except power users of quite small requirements. It was practically impossible for the Council successfully to take a supply in bulk. Even supposing the Council took a supply from the company they could employ that power successfully for the development of their present undertaking, if it was required for small power users, lighting and tramways; but directly they attempted to retail or rather distribute that supply to larger power users there would be a very substantial additional cost involved. That substantial additional cost would affect the price. The Council could not distribute it from their existing plant and mains, and it would involve very heavy expense. They could not supply the consumer without making a loss unless they charged him a higher price than the company charged. They were quite satisfied with the progress of the company up to the present. They were doing very well now, making very good progress indeed, but they had been extremely hampered and kept back until they got their Act of 1906. Radcliffe was just the place where a cheap supply was absolutely required. They could distribute in Radcliffe better than anywhere else because it was next door. All the districts around them were taking their supply.

By Mr. KEEN: The company were asking the Board of Trade to make the order in the ordinary form. The Board expressed the opinion that they must do that, and they would then deal with any limitation of powers. They wanted an order giving power to distribute direct to all power users above a reasonable limit, that limit being fixed at the size which the Council were not reasonably able or not likely to be reasonably able to deal with. They wanted all the clauses in the order with the scope of them limited for power purposes only and over certain limits. They did not ask even for limited power for lighting, as they had no wish to have power to take away from the local authority. They did not require the tramway load. Anything over 30 H.P. would be a very fair limit. Two orders for competitive powers of distribution in detail had been granted by the Board of Trade in a number of cases in the metropolitan area. He was not suggesting it would be right to grant a competitive order for all general purposes. The company were supplying Farnworth in bulk and they were distributing it to large power users. The most sensible plan for the Council to adopt was to give the company sanction to supply direct to power users above a certain size. He should imagine that in Radcliffe there should be 5,000 or 6,000 H.P. supplied within a few years. The company's station was not big enough yet. At present it was about 12,000 H.P., and they were putting down about 6,000 H.P. more. They had about 8,000 kw. installed, and they were installing 4,000 kw. They were selling electricity at a low price, and not at a profit which it should yield them and would have to do. Until they had got to a big station they were not getting best results. Witness was cross-examined as to the cost of generating at different works, and expressed the view that, other things being equal, a big generating station would generate at a lower cost than a smaller one. The Bury result (working cost 0·58d.) was very good. The company had no absolutely fixed charges. They got the best price they could. They had to deal with cases on their merits.

Mr. KEEN asked if Radcliffe Council decided to have a 6,000 H.P. station could they not raise the money much more cheaply than the company?—"I do not think you could raise it at all. I do not think you would be allowed either by the L.G. or by the ratepayers to raise £100,000." Assuming they got consent, he did not think they could raise it as cheaply, for the Council had to meet interest and sinking fund at a higher ratio. The company's sales of current realised £15,119 last year, the output being 7,055,000 units, sold at something over ½d. a unit. At present the company was making no loss.

Dealing with the suggestion that the company should be allowed to supply in Radcliffe in cases over 30 H.P., Mr. Keen asked what would be the Council's position if a firm laid plant down for 35 H.P. but only used 25.—The draft order would be prepared in a way to avoid any improper action on the part of users.

Mr. KEEN: A firm might originally take 25 H.P. from the Council and then increase it. When they passed 30 H.P. would it be fair for the company to step in and take that consumer?—Then make the limit 50 H.P. Or we would be prepared to consent to take none of the old customers of the Council.

Mr. J. L. RUSHTON, director of Dobson & Barlow, machinists, of Bradley Fold and Bolton, said that when his company selected the land on the boundary of Radcliffe they were greatly influenced in their decision by the fact that they could obtain a cheap supply of electricity there. They were now taking 300 to 400 H.P. from the company, and it was very satisfactory. He became a director of the company in 1910.

Mr. C. D. TAITE, manager of the Lancashire Electric Power Co., gave a list of the townships to which the company were supplying current in bulk, and said that one of them (Farnworth) started with their own generating plant, but had shut down their works. They were supplying firms in Prestwich and Bolton with the consent of the local authorities. One Radcliffe firm was being supplied (Messrs. Whittaker's) at Mount Sion, but he did not know whether they had Radcliffe Council's consent or not. The Power Company had agreements with Bolton and Salford for supplying in their districts. The units sold during the last quarter had increased by 46 per cent. and the revenue by 69 per cent., in comparison with the corresponding period of last year. When he became the company's manager in 1907 he considered the conditions laid down by Radcliffe Council in connection with the company were not workable. An agreement ought to have been arrived at between the two bodies for the benefit of power users. He put forward a case of the loss of a consumer of electricity to the company and an industrial firm to Radcliffe by the Council's policy of insisting upon negotiations for current passing through them. His experience was that the "third party principle" was unworkable. Being prevented from canvassing in the town they had to sit still and wait for customers, and a further difficulty was that they could not negotiate with persons looking for sites for works in Radcliffe, for they were unable to tell them definitely whether they could supply electricity, but had to say that they were controlled by the Council and had no appeal from the decision of that body. It was essential for the company to disclose terms of contract to the Council, and firms objected to their business matters becoming the subject of public discussion. Again, firms objected to asking the Council for something which they knew the Council could not give them. The Council could not compete with a large power company like their company. At the one Radcliffe works which the company supplied the current delivered for one motor was as much as the Council's total output, part from that required for the tramways. If the Board of Trade granted a provisional order to the company sanctioning their entry into Radcliffe and the company's order was limited to power users using over a certain limit there would be practically no competition with the Council. The company had difficulty in keeping on friendly relations with the Council, and had always worked under difficulties. There was a large demand for electrical energy in Radcliffe which the Council could not supply and which the company was anxious to deal with, and the absence of a cheap and large supply had a deterring effect upon the development of Radcliffe. It would also be the means of inducing new power users to settle in the district.

In cross-examination by Mr KEEN, Mr. Taite stated that they had only one large consumer in Radcliffe but there were two others prospective. Messrs. J. & J. J. Mellor were referred to the company by the Council. He thought Messrs. Mellor came to the conclusion they could do without electric power and the matter dropped. It was not due to any fault of the Council that Messrs. Mellor were not being supplied. About 2,200 kw. out of 4,000 kw. at their station represented large consumers in places where they had got provisional orders.

This closed the case for the Power Company.

Mr. H. WILKINSON, electrical engineer to Radcliffe Council, gave evidence in opposition to the application. The total capital expended on the municipal undertaking, he said, was now about £36,700. He handed in a statement as to the Council's power consumers and the capacity of the motors installed. Some of the small consumers were charged 2d. a unit, and all the bigger consumers (excepting the East Lancashire Paper Mill Co.) 0·9d. Any consumer taking 25,000 units per annum or over was allowed 10 per cent. reduction off the schedule price. The profits had annually increased, although depreciation was charged. The profit for the year ended March, 1909, was £473, and for March, 1910, £609, allowing over £400 for depreciation. In comparison with those of other Lancashire towns, Radcliffe's electricity works could be regarded as a satisfactory business undertaking. Bury was one of the few towns tha

Digitized by Google

could point to more satisfactory results, and they had the opportunity of coming to terms with Bury for a supply of current in bulk.

Mr. F. E. LACEY, consulting engineer, were of opinion that if the company's application for an order was granted as lodged it would be injurious to the Council's undertaking, and the open competition might result in the scrapping of their works.

Mr. S. J. WATSON, chief electrical engineer to Bury Corporation, said his Council would be able to supply electricity in bulk to Radcliffe, and were prepared to negotiate with them.

Coun. WALKER ALLEN, Chairman of Radcliffe Electricity committee, said the Council had acted reasonably with the Power Company, and he denied that the Council had been dilatory.

Other evidence was given and the case concluded.

STREET LIGHTING IN THE CITY OF WESTMINSTER.

Yesterday (Thursday), at a meeting of Westminster City Council, Mr. ABADY, chairman of the Works committee, moved the adoption of the following recommendations of the Works committee in regard to tenders received for street lighting :—

"That the lowest tender in each district—viz., that of the Gas Light & Coke Co.—be accepted for a term of five years, leaving for after consideration the settlement of what units of lighting shall be installed street by street, when only the actual figures of cost can be worked out ; and that the company be asked whether they are willing to continue the contract after the expiration of five years for a further period of five years, making 10 years in all, on the terms of the tender for 10 years, in the event of the Council so deciding and giving the company written notice not less than six months before the expiration of five years of the contract period that the contract shall be continued for such further period."

The electric lighting contracts in the Strand district, and in St. George's, do not expire until 1913, and are not affected by the above recommendations, but the district lighted by means of 71 arc lamps by the St. James' & Pall Mall Co. is affected.

It was stated that a petition had just been received from the ratepayers of the parish of St. James asking that the Council's decision on the matter should be deferred.

Mr. BINGHAM moved an amendment that the matter be referred back, although he still thought they had no alternative but to accept the gas company's tender ; but the inhabitants of Regent-street and Piccadilly were anxious that they should be quite sure they were going to give them as good a light as that now in Regent-street. It seemed to him, if they could maintain the candle-power, and it was equally effective, they ought to go in for gas. He had tried to read midway between two lamps in Fleet-street, and could not, but he could do so midway between two lamps in Regent-street.

Councillor FLINT seconded the amendment, so that the Council should be in harmony with the ratepayers. The result of the engineer's test was that the gas came out better under the photometer than the electric lighting taking it all through.

Mr. ABADY said both speakers had based their remarks on a misapprehension with regard to the arc lamps in Regent-street. It was proposed to remove these and put in their places on the same columns high-pressure gas lamps of a greater power than the light that at present existed, and they would be able to increase the light by about 50 per cent. at a cost which would be about 33⅓ per cent. cheaper than they could do it by electric light.

Mr. SPENCER SMITH said the electric lighting company had put up the price from £17 to £28 for the same light in the case of the 16 flame arcs.

Ald. EVERETT was in favour of deferring the matter for a fortnight. It was not fair to force this thing through without giving the ratepayers an opportunity of having their petition considered.

Mr. ABADY said there was no object to be served by deferring it. Someone must have got hold of an agenda, and, in the interests of one of the tenderers, gone into Regent-street shops and pitched a yarn about this being a retrograde movement.

Mr. WALLACE asked if it was suggested that the shopkeepers had no ideas of their own on the subject.

Mr. ABADY said the basis they had gone on to invite tenders was to fix units of 90, 180, 300, 1,800 an 3,000 c.p. One light was of the same value as another, except that one might be a nicer colour than another, in which respect he thought the advantage was on the side of gas, because when you got up to the high power units, which could only be produced by a flame arc, the electric light was a yellow colour, which he thought adversely affected shopkeepers. (A member : Quite the reverse.) The prices the gas company had quoted for each of these units was so much less than the prices of the electricity companies that they had no alternative but to accept the lowest tender. If they took a certain number of lamps of each of the capacities he had mentioned to make up a total of 400,000 c.p., they would get that for about 10 per cent. less than they now paid for 190,000 c.p. (viz., £13,000 a year). To do the same thing by electricity would cost £20,000. Fifty-three lamps with an aggregate candle-power of 50,000 cost £920 a year, and they could get double that candle-power for £7 more by gas, whereas 1,400 c.p. of electric lighting would cost £1,400.

An amendment, moved by Mr. PULMAN, "that the Council reserve the right to omit the lighting of Regent-street and Piccadilly from the contract" was defeated, as was also Mr. BINGHAM's amendment that the committee's recommendations be referred back, and a third amendment, by Ald EVERETT, "that the question of the 71 arc lamps in the Pall Mall district be referred back."

The committee's recommendations were adopted.

PARLIAMENTARY INTELLIGENCE.

WIMBLEDON & SUTTON RAILWAY BILL.

A Select Committee of the House of Lords, presided over by the Duke of Wellington, commenced on Friday the consideration of a bill to authorise the construction of an electric railway from Wimbledon to Sutton.

Mr. HONORATUS LLOYD, K.C., explained that the proposed line (5½ miles in length) would provide for an extension of the Metropolitan District Railway Co.'s electric train service, which at present ran from London to Wimbledon over a railway constructed by the L. & S.W. Railway Co., and on which there is also a steam service run by the latter company. The population of the district through which the line would pass, and which included Merton, Morden and Cheam, was between 110,000 and 112,000. There would be 10 stations. A great advantage of the proposed line would be that it would give communication with the whole of the London underground railways. The promoters were a local syndicate, and the proposed share capital was £350,000 and borrowing powers of one-third that amount. The engineer's estimate of the capital expenditure was £311,554. It was proposed that the District Co. should work the line, and that there should be a junction at Sutton with the L.B. & S.C. Railway if the L.B. & S.C. Co. so desired. There were petitions by two railway companies and also two by landowners against the bill, but the five local authorities through whose districts the line would pass supported the scheme.

On Monday numerous witnesses from the districts to be served by the proposed railway, including representatives of Wimbledon, Merton, Morden, Carshalton and Sutton Councils, gave evidence in favour of the scheme.

Mr. WM. VAUX GRAHAM, consulting engineer, gave technical details, and said the cost of the work was estimated at £181,140 and the land to be acquired was valued at £130,413.

Mr. PAGE, K.C., appeared for the L. & S.W. Railway Co., who objected to the proposed line, and said the junction proposed with their line was impossible.

On Tuesday Sir JOHN WOLFE BARRY said a Royal Commission recently expressed the opinion that it was not desirable that all railway passengers arriving in London should be discharged at one point, but that railways should be provided which would distribute them, and he thought the present project would assist in fulfilling that requirement. The curves and gradients were satisfactory, and the position for the station at Sutton seemed to be a suitable one. The railway would develop the district, and the Brighton Railway would derive benefit from it. He was satisfied with the prices on which the estimates were based. At first there would probably have to be interchange of traffic with the existing line at Wimbledon, but it would be preferable to project the trains forward from Wimbledon to Sutton. At another point on their system the South-Western Railway had extended their train service by a connection with the District Railway, and that was entirely on all fours with the present proposal.

Mr. A. R. COOPER, chief engineer of the District and other underground railways, said the drawings showed that the proposed line was well designed. He could see no objection to the District trains being projected forward from Wimbledon to Sutton as shown on the plans. There were curves on the District Railway as sharp as those shown on the plans. Per mile length, the gradients on the proposed line were more numerous than on the District Railway, but the stations had been so arranged that, except in one case, the gradients would be advantageous and lead to economical working, as they ran up into stations and down out of them.

Mr. R. H. SELBIE, general manager of the Metropolitan Railway, said the passengers on the Putney and Wimbledon line had increased, since the line was converted to electric traction, from 3,264,000 in 1906 to 5,460,000 in 1909. A similar traffic might be expected on the proposed line as the district became more developed.

Sir GEO. S. GIBB, chairman of the District and other underground railways, said no agreement had been entered into, but he thought the District Co. would undertake to work the new railway and use electric traction thereon.

Evidence was given that there would be no difficulty in raising the capital.

On Wednesday Mr. C. L. MORGAN, engineer in chief of the L.B. & S.C. Railway, said there were sharp curves and gradients on the plans of the proposed line. He would not say steam traction could not be used on it, but a slow speed and short trains would be required. He did not think the junction of the new line and the Brighton line would be for the convenience of the public.

Mr. FREEMAN, K.C. (for L.B. & S.C. Railway Co.) said the Brighton Railway carried passengers from Sutton to Victoria in half the time the promoters' line would take. A service of fast trains between Sutton and Wimbledon was tried some years ago, and was found not to be required. The estimate of the earnings was not justified, as the District Railway paid nothing on its ordinary capital.

Some residents in Sutton expressed the opinion that the new line was not required.

Mr. VICARY, assistant manager of the L. & S.W. Railway Co., objected to the proposed junction at Wimbledon, and Sir CHAS. OWENS, general manager, said the congested state of the line from Putney to Wimbledon would not allow of the proposed addition of trains.

Yesterday (Thursday) Mr. PAGE addressed the Committee on behalf of the L. & S.W. Railway. He said if the District Co. utilised the junction proposed, which left the South-Western line before reaching

Digitized by Google

Wimbledon station, the South-Western would have half their expenditure on the station thrown away, as the District Co. only paid towards the expenditure in proportion to the number of trains they stopped at Wimbledon. The bill was not truly in the interests of the public, and would do incalculable damage to the South-Western Railway.

Mr. LLOYD, replying for the promoters, said the Brighton Railway Co. had spoken of the territory as theirs, but Parliament had granted them no monopoly, and there was no real opposition from landowners, except in regard to a few gardens over which it would, unfortunately, be necessary to pass. The line from West Brompton to Putney was made through green fields, and there has been great development there as a result.

The chairman said the Committee had decided to allow the bill to proceed. They, however, made the following conditions: That the junction with the South-Western line is to be made by agreement, and, failing that, by arbitration; they do not insist upon the junction with the Brighton line at Sutton, but access between stations is to be arranged; the South-Western Co. are to receive a sum not less than at present for the user of the present Wimbledon terminal station, so that they shall not lose by the trains running past, whether they stop or not.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY BILL.

The consideration of this bill was continued by Lord Lamington's Committee on Friday.

Mr. D. HAY, consulting engineer to the promoting company, was examined in reference to the proposal in the bill to construct an extension from Charing Cross to the Embankment, where it is proposed to connect with the Baker-street line, and in reply to Mr. Szlumper, who appeared for the Gordon Hotels (Ltd.), said the proposed tunnel would pass the round end of the Hotel Metropole, facing the Embankment, at a distance of 6 ft. 6 in. from the wall. It could only be taken 2 ft. further away, and that would bring it directly in contact with the Baker-street tube. The tunnel would be 40 ft. below the surface at that point. He could not advise the promoters to accept a similar condition to that in the Baker-street Railway Bill of 1893, that there should be a cover over their tube at that part of the line of not less than 10 ft. of London clay.

Sir GEO. GIBB (chairman of the company) and Mr. L. R. VIGORS (surveyor) also gave evidence in support of the scheme. The former said if the condition as to the cover of 10 ft. of clay were imposed the whole project would have to be abandoned.

Lord BESSBOROUGH, chairman of the Gordon Hotels (Ltd.), and other witnesses were called in support of the theory that the Hotel Metropole, of which the Gordon Hotels (Ltd.) had an unexpired lease of 53 years, would be in danger of injury if the line were constructed as proposed.

The Committee rejected the scheme for making the loop line, but the other parts of the bill were allowed to proceed.

Mr. BALFOUR BROWNE (for the promoters) afterwards asked the Committee to restore the bill to the list, as communications had taken place between the Gordon Hotels (Ltd.) and the railway company, and it was now proposed to construct the tunnel some distance from the Hotel Metropole. The Committee complied with the request.

On Wednesday Mr. BALFOUR BROWNE informed the Committee that the promoters had come to an arrangement with the proprietors of the Metropole Hotel, but they were confronted with another difficulty, as the new plan provided for their going under the S.E. Railway Co.'s bridge at Charing Cross, and as Mr. Clode, counsel for the S.E. Co., could not say whether they would object, he thought it best to withdraw the proposal and come forward later with a properly devised scheme.

Subsequently the bill was allowed to proceed, but the portion relating to the loop from Trafalgar-square to the Embankment was deleted.

METROPOLITAN DISTRICT RAILWAY BILL.

The same Committee had before them on Monday a bill promoted by the Metropolitan District Railway Co.

The Hon. J. D. FITZGERALD, K.C. (for the promoters), said the bill sought power to construct two additional pairs of rails alongside the London & South-Western Railway Co.'s line (¾ mile in length) from Hammersmith to Turnham Green Junction and over which the District Co. and three other companies had running powers. An agreement had been come to with the South-Western Co. with regard to the construction of the new line. London County Council opposed because the promoters could not give them, in return for the ground they proposed to take for the erection of a viaduct to carry the railway through Ravenscourt Park alongside the old line, which is on a similar viaduct, an equal piece of land, to be thrown into the park. The existing railway, however, was constructed before the park was made, which should be in the company's favour. The additional width required was 27 ft.

Mr. A. H. STANLEY, general manager of the company, gave evidence as to the necessity for the additional lines. The District Co. ran 343 trains a day over the existing line.

The Committee decided that the bill should proceed.

BRADFORD CORPORATION BILL.

This bill, which seeks powers for the construction of four lengths of tramway and for various powers in regard to local administration and management, came before a Select Committee of the House of Commons on Wednesday.

Mr. HONORATUS LLOYD, for the Corporation, said that Bradford Corporation now owned practically every undertaking that it was practicable for a municipality to own, including gas, water, electricity and tramways, &c. The tramway clauses related to the construction of various new lines and the sanction of trackless cars, while there was also a proposal to carry goods and minerals upon the tramways. Four new tramways were contemplated in the bill. The next part of the bill dealt with the provision of motor omnibuses and powers to work them on the trackless system, and it was towards that that the opposition of the railway companies and carriers was mainly directed. There were many parts of the city where the public were clamouring for some means of access, but those responsible for the construction of tramways saw that the initial cost would prevent such enterprises from being remunerative for many years to come. Everybody was desirous of finding some more economical method of providing connection with the tramways that would meet the needs of these districts. A number of tramway experts had been abroad and had carefully investigated the railless tramway systems in vogue there. On the Continent the scheme was an assured success and worked admirably. One advantage was that it could be used as introductory to a permanent track when the traffic became heavy enough to justify such a step. The capital cost was from 20 to 25 per cent. of the cost of tramway construction, and many large centres were beginning to realise the convenience and economy of the method. General powers were asked for by Bradford, no routes at present being specified, these to be subject later to sanction by the Board of Trade or the L.G. Board. As to the actual running cost, the saving would be only about 1d. a mile, the main economy being in the capital charges. The Corporation regarded the Sticker-lane route as an example where trackless cars might be usefully adopted. The opposition was based to some extent on an objection to public money being spent on experimental undertakings, but the fact was that had long passed the experimental stage abroad. The Midland Railway Co. contended that it would be unfair competition, as the Corporation would be able to make up any loss out of the rates. But in point of fact it was with a view of avoiding any loss that the proposal was made. Bradford Corporation were not in the habit of being extravagant in these matters, for they had carried on their tramway undertaking in such a way as to make a profit in relief of rates, in spite of low fares and long distances, and the railway companies, so far from suffering loss from competition, would participate in the benefit by the reduction of the rates. They said the trackless trams would tend seriously to damage the surface of the streets. There would, of course, be ordinary wear and tear, but the Corporation would be liable to be rated to the full in respect of their earnings upon these routes, so that they would pay in rates for their share in the streets just as any other undertaking or ratepayer would. Then there was, of course, no serious danger of the overhead equipment damaging the bridges or signalling apparatus of the railway companies. A further objection taken was that it was not customary to grant powers of such a vague and wide character; but the object of the promoters was to provide for the needs of the public economically, and it would be too costly if for every little extension of this kind a special application had to be made to Parliament.

At a later stage Mr. Lloyd announced that the Corporation had been able to arrange their differences with the railway companies with regard both to trackless trams and the carriage of goods and minerals, subject to a safeguarding clause stating that the conveyance of those goods should be limited to such traffic as arose in and was destined for places within the city. Indeed, the tramways might be able to work in conjunction with the railways, the latter carrying from town to town and the tramways assisting in the local distribution. The establishment of the principle was agreed to, but that still left the opposition of the carriers and cab proprietors.

Mr. C. J. SPENCER (city tramways manager) said that the municipal tramways system comprised 54¾ route-miles and 99 miles of single track, 5½ route-miles being outside the city boundary. In recent years the Corporation had received many requests from people living in districts outside Bradford for instituting tramway services, but owing to the capital expenditure involved, and the probability that such expenditure would not prove remunerative, the requests had not hitherto been met. When the railless traction method came under their notice the Corporation appointed a committee to go abroad and inquire into it. With regard to the proposed new tramway routes, they considered that it would be desirable to instal the trackless system on that from Laisterdyke to Wakefield-raod, via Sticker-lane. The route, which would link up Brighouse and Bradford, was much desired by both towns. Powers for the line were obtained in 1901, but it was not constructed because a through route was not provided for. Reverting to the trackless tram proposals, Mr. Spencer gave particulars of the equipment and costs of working the railless system. Of all systems inspected by them he did not consider there was one failure. All were good, but some better than others. The capital cost of establishing a railless system in Bradford would, he estimated, be from £1,500 to £2,000 a mile, compared with £13,000 per mile, the cost of constructing an ordinary rail route. The weight of the vehicles, which would have a carrying capacity of 24 passengers, would be from 4¼ to 4½ tons, this being about half the size, carrying capacity and weight of an ordinary tramcar. With regard to cost, he took as an example the Sticker-lane route, which would be 1¼ miles in length, and estimated that the cost of the equipment would be £1,875. Five cars at £850 each would amount to £4,250, the total being £6,125. He estimated that the annual income would be about £4,000 and the annual profit £1,500. As to the upkeep of the roads, he said he had not calculated that in the cost, in view of the fact that the Corporation would pay rates and taxes on the route. The overhead equipment would be still available in case it should be found desirable to lay down rails.

The witness was cross-examined by Mr. POLLOCK, K.C., on behalf of the local carriers, and he admitted that some of the parcels were carried on motor vans and not on the tramcars. The cost of the parcels traffic was £6,322 last year and the net surplus £1,028. The great bulk of the parcels

Digitized by Google

went on the tramcars and were collected and delivered by boys, but with regard to a small portion of the parcels it was found convenient to collect and deliver them by motor vans. There was no sanction to purchase the motor vans for carrying parcels, but the Corporation felt they were necessary.

Mr. W. F. MARWOOD, assistant secretary to the Board of Trade, was questioned by the Chairman with regard to applications for general powers to establish trackless equipment, leaving the Board of Trade to prescribe the routes subsequently, and he stated that at present, when a corporation required to extend its tramways, it had to seek Parliamentary powers or apply for a provisional order in respect to each extension. In no case, he said, had power been left with the Board of Trade to prescribe the route, except with regard to short connecting lines.

Ald. THORNTON, mayor of Brighouse, stated that there was a strong desire in Brighouse that a tramway should be constructed to connect the town with Bradford. It was believed that it would prove very advantageous.

The Committee adjourned.

LEEDS CORPORATION BILL.

A Select Committee of the House of Lords, presided over by Lord Ritchie, yesterday (Thursday) commenced consideration of a bill to authorise Leeds Corporation to construct and run railless trolley omnibuses in the city.

Mr. J. B. HAMILTON (general manager of the Leeds tramways) gave particulars of the proposals. The route on which it was at present proposed to run the railless trolley vehicles commenced in the City-square and passed along Wellington-street, Aire-street and Whitehall-road to the city boundary at Drighlington. The estimates were £5,000 for construction of omnibuses, £9,000 for provision of electrical equipment and £300 for street improvements. Mr. Hamilton said the proposed system would be installed at one-fourth or one-fifth of the cost of ordinary tramways.

Mr. ROBERT ARMITAGE, M.P., and a member of the City Council, supported the proposal.

The Great Northern and the Lancashire & Yorkshire Railways, who opposed, said the powers were unprecedented, but there was no real competition proposed with them. The omnibuses would be less dangerous than ordinary tramways.

After some slight modifications had been made by agreement between the promoters and the opponent, the chairman said the Committee would report the bill, but it might be found necessary to make some slight alterations in the clauses in the House.

HANDSWORTH URBAN COUNCIL'S BILL.

Part III. of this bill, which came before a Select Committee of the House of Lords (presided over by the Earl Kintore) on Thursday last week, relates to the making of new tramways.

Mr. TALBOT, K.C., said the Urban Council of Handsworth owned a length of tramway in Holyhead-road (1,027 yds.) which was electrically equipped and leased to the South Staffordshire Tramways Co. for a term which expired next year. Electric current was supplied by the Council, which also owned another length of tramway, but to get by this to the centre of Birmingham it was necessary to go through Aston, where it had been necessary to obtain through running powers to avoid the charging of three separate fares to passengers. Next year the whole of the existing tramways would come into the possession of the Council. If the Council's scheme were to be carried out, powers should be granted now, so that the Council would be in a position to equip and electrify and be ready at the time when they would become the owners of the whole undertaking. The net cost of the tramways was estimated at £203,875, and the estimated revenue was ample for sinking fund, interest and depreciation.

Mr. ALFRED SANDAS, chairman of the Urban Council, gave evidence, and said that the existing tramways would fall into the hands of the Council in June. They must get some alternative to go round Aston or they would be at the mercy of Aston and Birmingham.

Mr. GEORGE CONATY, tramway engineer, said the proposed tramway formed the necessary link with districts which were rapidly growing

Sir A. B. W. KENNEDY, consulting engineer to the promoters, said he had prepared the estimates. The new tramways were intended to link up existing tramways to Birmingham. The large residential district of Handsworth had not hitherto had tramway facilities. The new tramways would form part of the system of through east and west running. He estimated the revenue at 7¼d. and the working expenses at 6¼d. per car-mile, and the residue would meet capital and running charges and depreciation. Taken as a whole, he thought these tramways would be successful.

For Birmingham Corporation (who opposed), Mr. ALFRED BAKER, manager of the Corporation tramways, said the tramway proposals of the bill were unnecessary. Handsworth were losing £3,000 per annum on the piece of line they had, and under the proposals of the bill would lose more. Birmingham working expenses were 7¼d. per car-mile. He did not think Handsworth could run at less than 7¼d. Birmingham was itself suffering from piecemeal construction of tramway undertakings.

Other evidence having been called, the Committee found the preamble of the bill proved and passed its tramway clauses.

Devonport & District Tramways Bill.—This bill, which was promoted by the Devonport & District Tramways Co. for modifying the terms of the lease under which the company worked the Corporation tramways, was rejected by the Select Committee of the House of Commons last week.

Telephone Charges.—The Postmaster-General (Mr. H. Samuel) has promised to furnish a return, moved for by Lord Claud Hamilton, showing the telephone charges in operation in this country and abroad.

Trans-Atlantic Cables.—In the House of Commons last week Mr. J. P. Boland asked the Postmaster-General whether he was aware that considerable damage was still being caused to the trans-Atlantic cables by the operations of steam trawlers off Ballinskelligs Bay, and whether, in view of the fact that a number of cables had had to be renewed, and that it was now proposed to lay two new cables, he could state what steps would be taken to prevent damage in the future.

In reply, the Assistant Postmaster-General (Capt. NORTON) said that the most recent case brought to his notice of damage to a trans-Atlantic cable attributable to the operation of steam trawlers occurred in November last. The Inter-Departmental Committee which considered the question in 1908, reported in favour of the inspection of trawling gear as the most practical means of minimising the damage. Such a system of inspection was now in force at the ports concerned throughout the United Kingdom.

LEGAL INTELLIGENCE.

Anns v. Walker.

On Friday the Court of Appeal (Lords Justices Vaughan Williams, Moulton and Farwell) dismissed the application of defendant for judgment or new trial in this action, which was tried before Mr. Justice Grantham and a special jury. The action was brought by plaintiff, Mr. Albert Anns (secretary of the National Telephone Co.) against defendant (Mr. T. C. Walker), who was formerly head of the share department of the company, for alleged libel. Defendant pleaded justification. Plaintiff's counsel only asked for nominal damages, and the jury returned a verdict for him for 20s. Judgment was entered accordingly, and Mr. Justice Grantham granted an injunction restraining defendant from publishing similar libels.

Illuminated Advertisements.

Last week before a Divisional Court (the Lord Chief Justice, Mr. Justice Channell and Mr. Justice Bray), Mr. DALDY, on behalf of London County Council, applied for a rule nisi for a mandamus directed to the police magistrate at Marylebone requiring him to state a case for the opinion of the Court. A summons had been taken out by London County Council against W. Sandorides & Co., under sec. 73 of the London Building Act, 1894, in respect of an illuminated sign on premises in Oxford-street. The sign projected about 3 ft. from the building. The magistrate found that in point of fact the sign was a projection, but he considered himself bound by the decision in Hull *v.* London County Council and London County Council *v.* Schewzik; he held that it did not come within the section and dismissed the summons. Counsel submitted that the sign really formed part of the building, and that it was impossible to apply the principle of the cited cases to the case. The magistrate had not directed his mind to the question whether the sign was a projection forming part of the building.

The LORD CHIEF JUSTICE said that they would grant a rule, but he thought it might turn out that the magistrate had decided the question as one of fact with a perfect appreciation of the question of law involved. His Lordship thought that the true construction of sec. 73 (8) of the London Building Act, 1894, was that it dealt with parts of a building and not with mere projections from a building. It was, however, important that there should be no misunderstanding about the case, and the rule would therefore be granted.

Boulton v. Perry & Co.

The contract for the electric lighting and power installation at the Piccadilly Hotel came before Mr. Justice Hamilton last week in an action by Mr. S. A. Boulton (as assignee of a debt due to Blackburn, Starling & Co., Ltd.) against Messrs. Perry & Co. to recover £2,557. 9s. 10d. alleged to be due from defendants to Messrs. Blackburn, Starling & Co. The sum claimed was the amount certified by Mr. E. W. Bowles, consulting engineer of the Piccadilly Hotel, to be due to Messrs. Blackburn, Starling & Co. as the final instalment of payments for the electric lighting and power installation at the hotel. Defendants pleaded that it was a term of the contract between them and Messrs. Blackburn, Starling & Co. that defendants should only be liable to pay when they received the money from the Piccadilly Hotel. To this plaintiff replied that if defendants had not received payment it was because they departed from the terms of their contract, and were thus unable to obtain the certificate for payment.

Mr. Scrutton, K.C., and Mr. M. Hill for plaintiff; and Mr. J. A. Simon, K.C., and Mr. R. F. Colam for defendants.

Mr. SCRUTTON said so far as he could understand the matter, which was somewhat complicated, Mr. Bowles, who ought under the contract to have certified for 100 per cent. of the electric light work that was done, never did so, but only certified for a lump sum, which included 80 per cent. of the electric work. He then sent the certificate to Mr. Woodward, the architect, who added 15 per cent. to it, and included it in a lump sum which covered other items, and gave the certificate to Messrs. Perry & Co. This was for a large sum, some £27,000 or £30,000. Messrs. Perry & Co. were bound to get from the Piccadilly Hotel Co. a certificate for the full value of the electrical work done from time to time, and their contract would enable them to do so if it was enforced.

Digitized by Google

His LORDSHIP: You say that whether you or Perry & Co. misunderstood the contract does not matter, and that defendants must be treated as not having insisted on their rights.

Mr. Scrutton agreed.

Mr. COLAM said the question was whose duty it was to get the certificate from Mr. Bowles. In fact, he thought it was the duty of Blackburn, Starling & Co..

Mr. SIMON said it was absurd to say that it was defendants' fault that the money had not been paid to them. Of course, Messrs. Perry had always recognised that when they got the money they must pay it to the sub-contractors, but they had not got it, and therefore he submitted they were not called upon to pay.

His LORDSHIP, in giving judgment, said plaintiff now made two points: (1) that a condition precedent was fulfilled prior to the commencement of the action and (2) that by delivering a reply subsequent to the decision on the preliminary issue he contended that if that condition precedent had not been fulfilled defendants themselves were responsible. Defendants wanted him to come to the conclusion that the contract was varied by consent, but he did not think he could do that on the evidence, and he must proceed on the footing of the formal contract. It was merely a question whether the payments had been received of the amount mentioned in the engineer's certificate. He came to the conclusion that it was the business of Blackburn, Starling & Co. to get the certificate and not that of Perry & Co., and he found no evidence of obstruction, interference or hindrance on defendants' part. His Lordship gave judgment for defendants, with costs.

Stay of execution was granted.

Electrical Co. (Ltd.) v. O. H. Thomas, Son & Co.

This action is still proceeding before the Official Referee, Mr. Pollock, and is expected to last some time yet. It will be remembered that plaintiffs sue defendants for balance of the price of an electrical pumping plant which they contracted to put down in defendants' coal mine in the Llynm Valley, South Wales. The plant was required to replace a steam pumping plant and to unwater the mine. Defendants refused to satisfy plaintiffs' claim because, they alleged, the plant supplied was inefficient and did not carry out the work required of it, they counterclaimed for some £30,000 damages in respect of this alleged non-efficiency. The case has had a hearing of 28 days in London and five days in Swansea. The Referee is now dealing with the counterclaim, and plaintiffs are adducing evidence to show that the mine never could have been worked at a profit and that the cost of working coal was some 50 per cent. more than the f.o.b. selling price.

We are informed that the cost of this lengthy action has already amounted to between £8,000 to £10,000.

Mr. Thomas, K.C., with Mr. Sankey, K.C., are counsel for the Electrical Co., and Mr. F. Williams, K.C., with Mr. Meager are for the defendants.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Torquay Town Council invite applications from qualified engineers for the position of borough electrical engineer. Commencing salary £250, rising to £300 per annum. Applications to the town clerk, Mr. Fredk. S. Hex, Town Hall, Torquay, by Saturday, April 23. See also an advertisement.

An assistant is required in the engineer-in-chief's department of the Westminster Electric Supply Corpn., to calibrate and keep in order all instruments and telephones in the company's generating stations. Commencing salary £120 per annum. Applications by the 25th inst. to the Engineer-in-Chief, Eccleston-place, London, S.W. See advertisement.

A leading draughtsman is required by a first-class electrical firm, to take charge of drawing office; must be used to h. and l.-t. switchgear. See advertisement.

A draughtsman is wanted for switchgear design, both h. and l.-t. See advertisement.

A responsible position in a scientific apparatus factory is vacant. Applications to Messrs. Reynolds & Branson (Ltd.), 14, Commercial-street, Leeds. See an advertisement.

The Committee of Visitors of the Essex and Colchester Lunatic Asylums require an engineering clerk of works, under the direction of their architects and consulting engineers, during the installation of electric lighting machinery, mains, wiring, telephones and heating apparatus, &c., at their new Asylum, Mile End, Colchester. Applicants must be capable of taking charge of the installation when completed. Salary as Clerk of Works £4 per week. Application forms from the clerk to the Committee of Visitors (Mr. Walter Payne Gepp), Essex and Colchester Lunatic Asylums, Chelmsford, to whom applications by April 28.

Swindon Corporation require an assistant electrical and mechanical engineer for their electricity and tramways departments. Applications by April 22.

Applications are invited for the position of principal of the Wolverhampton Technical School. Commencing salary £350 per annum. Applications (by May 5) to Mr. B. H. Preston, Town Hall, Wolverhampton.

Mr. E. S. Taylor, of Watford electricity works, has resigned, and Mr. J. E. Walley, engineer-in-charge, has been appointed to the vacant position at £110 per annum, rising by annual increments of £10 to £130. Mr. R. S. Savory (improver) has been appointed assistant mains superintendent and Mr. J. B. Dent engineer-in-charge.

Mr. H. H. Jeffcott, head of the meteorology department of the National Physical Laboratory (Teddington) has been appointed to the chair of Engineering in the Royal College of Science, Dublin.

Sheffield Council has appointed Mr. H. G. Bennett, motor canvassing engineer in the wiring and fittings department, to be chief motor assistant at £160 per annum, rising by annual increments of £10 to £180.

Mr. A. R. Chaytor has been appointed assistant mains superintendent to the Yorkshire Electric Power Co.

EDUCATIONAL NOTICES.

Summer School Lectures.—Glamorgan Education committee have arranged short summer courses of lectures during August, as follows: (1) Practical surveying course at Penarth; (2) Engineering course; Mining, mechanical and electrical engineering (laboratory work) and practical mathematics; (3) Metallurgy course: Metallurgy, chemistry and practical mathematics; (4) Teachers' course: Geology (lectures and field work), physics and chemistry (this course has been arranged to meet the requirements of teachers engaged in or preparing for technical work at evening schools or technical schools); (5) Evening lectures for colliery firemen on explosives and shot-firing; (6) Evening lectures on electricity in mines. Courses 2, 3, 4, 5 and 6 will be held at University College, Cardiff, the other courses at the County School, Penarth. Certificates will be issued to successful candidates. Particulars and admission forms from 35, Park-place, Cardiff.

Crystal Palace Engineering Society.—The Wilson premium for the best Paper read before this society during the present session has been awarded to R. Hook for his Paper on "Narrow Gauge Railways." The premium was presented to Mr. Hook by Sir Charles Rivers Wilson, G.C.M.G., C.B., on Tuesday last.

Barking.—The output of the electricity department for the year ended March 31 was 1,622,485 units, an increase of 38,772 units. The units sold were 1,374,960 an increase of 37,616.

Battersea (London).—Additional low-tension cables are to be laid in Nine Elms district and other work is to be carried out at a cost of £8,895. As there is an increasing demand on the route of the feeder cable from the station to Wellington-road a 0·5 sq. in. concentric feeder cable is to be provided and drawn into the spare conduits already fixed at a cost of £650.

Bexhill.—The Parade is to be lighted electrically at a cost of £226. Sanction has been received to loans of £137, excess expenditure, £3,260 expenditure on mains (20 years), and £600 for services (15 years). With certain unexpended balances of previous loans, the total now available for mains is £4,542.

Birkenhead.—At the last meeting of the Corporation the Electricity committee recommended that the charge to electricity consumers in Bidston, Noctorum, Upton and Prenton be reduced from 7d. to 6d. per unit. Mr. Russell moved that this report be not confirmed, and after discussion the amendment was carried.

Birmingham.—The Electric committee propose to hand over, in relief of rates, £10,000 out of the last year's profits of the electricity undertaking.

Canadian Water Power.—In a recent communication from one of the leading engineers in Canada our correspondent writes that there is in Quebec Province alone, he estimates, about 20,000,000 H.P. of water power awaiting development. This is taking into account only the known water courses in the Province.

Cookstown.—By a majority of one the Council have decided to postpone their proposed electricity scheme until the housing scheme has been settled.

Custom Duties.—The Belgian Minister of Finance recently introduced in the Chamber of Representatives a bill to make alterations in the import duties on various goods, including an increase in the duty on "electrical machines of cast iron" from fr.2 to fr.4 per 100 kilogs (1s. 7½d. per cwt.)

A Presidential proclamation has been issued extending the benefit of the U.S.A. minimum tariff to all British Colonies and possessions not hitherto mentioned.

Digitized by Google

Derby.—An inquiry was held on Wednesday into the application of the Council for sanction to borrow £5,203 for the electricity undertaking.

In support of the application it was stated that in 1908-9 there was an increase of 600,000 units in the demand, and a similar increase was anticipated in the present year. A tender had been conditionally accepted for laying down additional plant, including generators (£4,076), conversion plant (£1,027) and contingencies (£100).

Dowlais.—It was reported at the last meeting of the Dowlais Chamber of Trade that the Merthyr Electric Traction & Lighting Co. had consented to lay underground cables in all the narrow areas and thoroughfares, and overhead wires would be fixed in no street less than 22 ft. wide.

Eastbourne.—An unopposed inquiry was held on Tuesday into the Council's application for sanction to borrow money for condensing plant at the electricity works.

Edinburgh.—It has been decided to adopt electric lighting for the common stairs in High-street, Cowgate and Canongate districts. The cost will be 21s. per lamp, against 17s. 6d. for incandescent gas.

Exhibition.—An Exhibition of Applied Electricity will be held at Nymegen (Holland) from July 2 to Aug. 15 next. Applications for space can be sent to 18, Kelfkensbosch, Nymegen. Regulations, &c., may be seen at 73, Basinghall-street, London, E.C.

French Government Telegraphs.—The Louis-Dakar submarine cable has been acquired by the French Government.

Gillingham.—An inquiry was held on Tuesday into the application of the Council for sanction to borrow £3,000 for additional generating plant, including a Diesel oil engine and dynamo.

Glasgow.—The Corporation have adopted the report of the Electricity committee (abstracted in our last issue) recommending that steps be taken to acquire a site for an additional generating station.

Glasgow-Kirkintilloch Tramways.—At a public meeting last week a deputation was appointed to wait upon Kirkintilloch Council to urge them to take immediate steps to open negotiations with Glasgow Corporation to extend the Glasgow tramway system from Bishopbriggs to Kirkintilloch.

Hampstead (London).—It has been decided to convert 317 street lamps from gas to electric lighting. The annual charge per lamp will be £2. 19s. 6d., against £3. 4s. 9d. for gas.

Honduras.—A concession has been granted to Mr. J. W. Grace authorising the Puerta Cortez and Baracoa Electric Co. to supply electrical energy in Puerta Cortez and Baracoa, and Mr. M. E. Lardizabel has obtained a similar concession for the Empresa de Luz Electrica de San Pedro-Sula in respect of Pedro-Sula town.

India.—"Indian Engineering" says a motor-generator set, control panels, &c., for the East Indian Railway workshops at Lillooah have been ordered from England.

The "Indian and Eastern Engineer" states that final estimates for he Simla hydro-electric scheme show that the total cost will be about 9½ lakhs of rupees (£63,333).

The Railways Board have given general approval of proposals to adopt electric driving in the Kanchrapara and Saidpur workshops of the Eastern Bengal State Railway, and to provide electric fans for the N.W. Railway offices at Lahore.

Italy.—The Societa Anonima Compagnia Italiana dei Grandi Alberghi, has obtained a decree authorising the construction and working of various sections of electric tramway on the Lido (Venice.)

Japan.—A company has been formed to construct an electric railway from Tokio to Yokohama, about 15 miles in length, and a branch to Kamata nearly four miles in length. The overhead system will be adopted, and the line will be double track and of 3 ft. 6 in. gauge. The cost of construction will be about £357,300. Further particulars can be obtained at 73, Basinghall-street, E.C.

London Chamber of Commerce.—At the annual meeting last week the Electrical Trades' Section reported that Mr. C. P. Sparks had been re-elected chairman, and Mr. W. J. Madgen deputy-chairman.

In regard to electricity in factories, as the Home Secretary, in issuing the Regulations, did not adopt all the recommendations made by the Commissioner, including that headed "Arbitration, Appeal or other Protection," the Home Office were approached with a view to receiving a deputation on this matter, but, finding the Department were unable to take any steps until the general law had been amended, it was not possible to take any further action in the matter. Members were, therefore, advised that the only further precaution that could be taken was to apply for exemption in those cases, at any rate, where there was a difficulty in applying the regulations. Such exemptions could be obtained under exemption No. 6.

In regard to electricity in mines and the appointment of a Departmental committee, a communication was addressed to the Home Office suggesting that there should be a representative of electrical manufacturers and electric supply undertakers, to advise more particularlyion the commercial aspects of the regulations. The committee appointed by the Home Office was small, but met with the approval of the electrical industry. The section considered the advisability of arranging for a witness to give evidence as to the working of the existing special rules for the use of electricity in mines, but up to the end of the year such witness had not been secured, and further steps were being taken in this direction.

The section considered the question of the installation of wireless telegraphy on passenger ships, and a resolution was unanimously passed to the effect that it was advisable that all passenger ships for oversea traffic should be fitted with wireless telegraphy. The Council of the Chamber was requested to urge his Majesty's Government to introduce a bill containing a compulsory clause.

The section approved the action of the manufacturers' section in opposing the proposal of London County Council to promote legislation to delete the word "black" from the clause in the Public Health Act, 1891, which provides that "any chimney (not being the chimney of a private dwelling house) sending forth black smoke in such quantities as to be a nuisance shall be a nuisance to be dealt with summarily under the act."

It was reported to the section that the Council had appointed a special committee in connection with the question of misrepresentation in trade, and would be willing to receive suggestions as to points affecting electrical manufacturers which might usefully be brought before the committee, and a witness was appointed to give evidence on behalf of the section before the special committee.

Manchester.—On Wednesday the Electricity committee recommended the Council to apply for sanction to borrow £40,000 for extensions of the electricity undertaking.

Ald. HOLT said the committee ought to be placed on the same footing as the other trading committees, and asked to pay more in aid of the rates. The Corporation had spent about £2,000,000 on the electricity undertaking and ought to have a better return. The Electricity committee were placing the Gas committee in a very unfair position.

Mr. HOWARTH, chairman of the Electricity committee, said the department was not instituted as a trading department, but to provide current which the citizens could not provide for themselves. The operations of the committee would be limited if they were compelled to pay a given sum every year in aid of rates. He did not think the Gas committee were justified in paying the large amount they did in aid of rates. The desire of the Electricity committee was to encourage firms to open works in the city.

Ald. HOLT moved that the Electricity committee's proposal be referred back, but after discussion the recommendation was adopted.

At the meeting of the City Council last week Mr. Thos Hudson, deputy town clerk, was appointed town clerk, in succession to Sir W. H. Talbot, who has been retained as consulting solicitor.

The traffic revenue of the Corporation tramways for the year ended March 31 amounted to £777,220, an increase of £3,185 over 1908. The number of car-miles run was 17,181,774, against 17,316,753. The number of passengers carried was 159,049,696 against 155,011,884.

Marylebone (London).—At the meeting of the Council last week Councillor Duncan Watson moved "That a committee be appointed, composed of the chairmen of the standing committees, to inquire into the complaints made by electrical contractors of the methods of the sales department of the electricity undertaking."

Mr. WATSON said he objected to the sales department carrying on that which was nothing more or less than municipal retail trading; it was speculative, and was detrimental, not only to the undertaking, but to the ratepayers who were contractors.

In reply to the statements by Mr. Watson, Ald. DEBENHAM, chairman of the Electric Supply committee, said the Borough Council decided three months ago that it was necessary to have a sales department so as to increase the sale of electric current; and the interests of the Council could never be the same as those of electrical contractors. It was not to the detriment of the latter, but rather did the figures prove the contrary, for active business made it good for everyone. The committee did not compete with contractors or cut prices, and although Marylebone had the largest number of electrical contractors, yet she had the biggest number of "dead services."

The motion did not receive much support, and ultimately it was rejected by a large majority, only four voting for it.

Palestine.—The "Daily Mail" announces that a scheme has been prepared by a French Company for supplying the whole of Palestine with electricity. Water power will be obtained from a fall on the Jordan between the Waters of Merom and the Lake of Galilee. The generating plant will be erected on the west bank of the river, and electricity will be transmitted to all the chief towns of the country.

Personal.—Mr. Justus Eck, engineer-in-chief to the Union Electric Co., Park-street, Southwark, S.E., sailed on April 9 by the ss. "Lusitania," for New York, with the intention of visiting the principal cities of the United States, for studying the latest American developments in street, shop and railway lighting, and in the applications of electricity to manufacturing and mining.

Mr. Henry C. Adams, junior partner in Henry Adams & Son, had the honour of being the first candidate elected a fellow of the Society of Engineers, the president and council being already fellows under the articles of association.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Dr. J. Erskine-Murray asks us to state that the rumour that he has been appointed technical adviser to a wireless syndicate is untrue and calculated to injure his position as an independent consultant. He has no pecuniary connection with, or interest in, any particular system, his relations with all his clients being on the same basis, namely that of an occasional consultant.

Plymouth.—Cable extensions, estimated to cost £170, are to be made. Twelve metal filament lamps are to be installed in the market, the annual charge for which will be £2. 15s. per lamp.

Presentations.—On 1st inst. Mr. G. F. Craven, chief assistant tramways engineer to the Reading Corporation, was presented with a silver tea and coffee service by the employes and staff of the tramways department, as a mark of esteem and good wishes on his approaching marriage. The general manager (Mr. W. Binns) made the presentation.

Morecambe Borough officials have presented a kit bag to Mr. W. H. Hall, late borough electrical engineer.

Gravesend electricity staff have presented a gold mounted ebony walking stick to Mr. P. W. Naylor, who is leaving.

Provisional Order Revocation.—The Board of Trade have revoked, as from April 4, the Renfrew Burgh Electric Lighting Order 1905.

St. Anne's-on-the-Sea.—The following revised scale of charges for electric current has been adopted :—

Lighting : Maximum demand system, 6d. and 2d., instead of 7d. and 2d., or flat rate 4¾d., instead of 5¼d. Heating, power, &c. : First 200 units 2d. per unit, and for each additional unit 1½d., instead of 2½d. for first 100, 2d. for second 100 units and 1½d. after. A discount 5 per cent. is allowed for prompt payment.

Councillor HODGKINSON said : After making the reductions, there would still be £500 for relief of rates, bringing the sum so granted up to £4,000 in all. But it would be unfair for electricity users to have to pay an unreasonable price so as to provide funds to relieve gas users. Metal filament lamps and the revised scale made electricity compete with gas. The electricity undertaking was in the hands of an engineer (Mr. Clothier) who was worthy of a better post, and the successful results were largely due to his capable management.

The Council have agreed to contribute £20 towards the cost of promoting a bill to give local authorities power to undertake wiring work, &c.

Scholarships.—The London Inter-Collegiate Scholarships Board announce that an examination will be held on May 10 for 20 entrance scholarships and exhibitions of an aggregate total value of about £1,500 open to men and women, and tenable in the faculties of arts, science and engineering of University College, King's College and the East London College. Particulars from the Secretary (Mr. A. E. G. Attoe), University College, Gower-street, London, W.C.

Sheffield.—An agreement has been arrived at between the Electric Light committee and the Yorkshire Electric Power Co. with reference to the supply of electricity by the Corporation to certain premises in Tinsley.

The Electric Light committee recommend that the salary of the general manager of the electric supply department (Mr. S. E. Fedden) be increased from £800 to £900 per annum.

Southport.—In future the Tramways and Electricity undertakings will be controlled by one committee. Mr. A. S. Black remains borough electrical engineer and tramway manager, and Mr. T. Kendrew becomes deputy electrical engineer and tramway manager.

Spain.—The Cia del Tranvia Urbano de Bilbao have applied to the Direccion General de Obras Publicas, Madrid, for a concession to construct and work an electric tramway in Bilbao. The company have already obtained a concession for an electric tramway in another part of the city.

Swindon.—Mr. R. W. Grubb, the assistant electrical engineer, recently obtained an appointment at Dewsbury, and a successor is being advertised for.

Taunton.—The borough electrical engineer (Mr. E. B. Thornhill) has tendered his resignation.

The Rubber Boom.—In a well-reasoned review of the rubber situation the "Financial News," of the 12th inst., deals with the question of the effect of the great rise in the price of rubber shares and in the value of rubber properties on th revenue of the Eastern and Associated Telegraph Companies, and the Indo-European Co. (and, incidentally, other cable companies) arising out of this boom. The approaching issue of the Eastern Telegraph Co.'s report and accounts for the current half-year is made the occasion of an interesting résumé of the company's financial position, stress being laid upon the conservative policy of the directors in regard to the building up of substantial reserves.

Thurstonland (Yorks).—The Council have asked the Yorkshire Electric Power Co. to submit terms for the supply of electricity.

Tramway Men's Hours.—On Tuesday the Parliamentary committee of the Trade Union Congress waited upon the Parliamentary Secretary to the Board of Trade (Mr. H. J. Tennant) to lay before him matters affecting tramway men.

Mr. G. T. JACKSON, general secretary of the Amalgamated Society of Tramway and Vehicle Workers, said the question he had to submit was a reasonable one—namely, that the men should be allowed a minimum rest time of eight hours between the time of finishing their day's labour and taking up duty again. The system which prevailed split the men's time into, perhaps, three, four or five hours. The men journeyed once or twice in a car, were taken off, and put on again. He contended that to compel a man to spread his labour over 14, 15 or 16 hours a day for five days of the week was most unreasonable. The health of the men had been greatly affected by the long hours, and he suggested that the Board should ask for a return from the various tramway authorities, showing the system under which the day's labour was performed, the number of hours the men had to work, and the spread-over period to get their time in.

Mr. TENNANT, in reply, said he agreed that an eight hours' interval was a reasonable request, but there were difficulties with regard to the powers of the Board of Trade. They had wider powers in relation to railways than in relation to tramways. They could insist upon certain things on railways with regard to drivers and engines, but they had not similar powers in relation to the drivers of tramway cars. It had been stated that it was a common practice in certain trades to come to an agreement with employers in relation to an eight hours interval, and he suggested that the tramway men should come to a similar arrangement.

Mr. JACKSON said they had tried that method and failed. The only course that might be open to them was to withdraw their men. They would not do that unless they were driven to it.

Mr. TENNANT wished them to understand that the Board of Trade had no absolute powers of compulsion in the matter. If hard cases were brought to their notice, they would be glad to make representations to the Corporations employing the men. He could not make any promise with regard to advocating a double shift.

Venezuelan Coast Cables.—The "Journal Telegraphique" has announced that the following coast cables of the Cie Francaise des Cables Télégraphiques have been transferred to the Venezuelan Government :—Guayra to Puerto Cabello, la Vela to Coro à Maracaïbo, la Guayra to Carenero, Carenero to Guanta, Guanta to Cumana, Cumana to Porlamar, Porlamar to Carupano.

Watford.—Arrangements have been made for supplying electricity in Munden.

Wilmslow.—The Council have renewed the agreement with the Alderley and Wilmslow Electric Supply (Ltd.) for public lighting for another five years. The company undertakes to carry out improvements in the lighting of the main roads. Extensions have been passed for other districts, and it is stated that when these have been made nearly the whole of the main road from Manchester to Alderley will be lighted.

Wireless Telegraph Notes.—The British Vice-Consul at Ymuiden, Holland (Mr. S. C. L. Reygersberg) reports particulars of an interesting experiment made recently in fitting several steam trawlers with wireless telegraph apparatus, enabling them to communicate with the State wireless station at Ymuiden. The experiment seems to have been thoroughly successful, one experience in particular showing its value. During the dock strike that occurred in the autumn of 1909, steam trawlers at sea were warned not to return to Ymuiden harbour, but to proceed to British or German ports with their catches. It has also been found possible for the smack owners on shore to direct the trawlers at sea towards shoals of fish, of which information is received from the craft that arrive at Ymuiden.

The "Yorkshire Post" of 11th inst. states that, although the Board of Trade has repeatedly refused an inquiry into the various systems of wireless telegraphy, a Departmental Committee is about to be appointed with the view to the preparation of a measure to make wireless installation on board ocean-going passenger ships compulsory.

What is described as the first wireless message to be communicated between New Zealand and Australia took place on the 25th Feb., when Mr. J. H. A. Pike, who operates a private licensed station at Arncliffe, received a wireless message from H.M.S. "Powerful," which vessel had left a few hours previously the harbour at Auckland. Mr. Pike claims that with low aerial wires (50 ft.) he is able, by means of a specially sensitive detector he has invented, to obtain communica-

Digitized by Google

tions which are not possible by any other means, and that he has "heard" messages from the "Powerful," said to be the best equipped vessel in Australian waters, a distance of over 1,350 miles.

The story goes that the undergraduates at Harvard University, U.S.A., have erected five wireless stations with the purpose of giving instruction and experience to the students, who are reported to have organised a joint stock company, and to have erected their central station in Holyoake House. The entire outfit is reported to be of the most modern type.

Wolverhampton.—The Corporation have approved a report of the Electricity committee, recommending that, owing to the continuously increasing demand for electricity, extensions of the generating plant at the electricity station and also the laying of additional distributing mains at a total cost of £23,000 be proceeded with.

The chairman of the committee (Mr. Gough Allen) explained that the maximum load had increased from 1,775 kw. in 1906-7 to 3,880 kw. in 1909-10. In consequence of the necessity of providing the machinery, tenders had been advertised for, and he hoped the committee would be allowed before the next Council meeting to accept a tender.

Workhouse Lighting.—Fulham (London) Guardians have decided to wire the administrative block of the Belmont workhouse at Sutton.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding **that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable** and of little value for **Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.**

TENDERS INVITED.

West Bromwich Electricity committee invite tenders for supply, delivery and erection of a 750 kw. d.-c. turbo-generator and surface condenser. Specification, general conditions, forms of tender, &c., from the borough electrical engineer (Mr. W. A. Jackson), Electricity Works, West Bromwich. Tenders to the Chairman of the Electricity committee, Town Hall, West Bromwich, by May 2. See also an advertisement.

The Secretary of State for War invites tenders for the supply of two plants for the production of hydrogen and oxygen by the electrolysis of water at the Balloon Factory, South Farnborough, Hants. Forms of tender from the Director of Army Contracts, War Office, Whitehall, London, S.W., where tenders are to be delivered by noon of May 4. See also an advertisement.

Hammersmith (London) Council invite tenders for supply of circular stoneware cable ducts, with Stamford joints, 1,750 yds. of 0·25 h.t. concentric cable, and prepayment meters. Specifications, &c., from the borough electrical engineer (Mr. G. Gilbert Bell), 85, Fulham Palace-road, Hammersmith, W. Tenders to the town clerk (Mr. H. Thompson), Town Hall, Hammersmith, W., by 4 p.m. April 20. See also an advertisement.

Tenders are required by June 8, 1910, for the supply of six sections of common battery switchboard and equipment jumper wire and cable to the Postmaster-General's department in Queensland. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited, up to May 18, for the supply of paper insulated lead-covered and brass ribbon taped cable to the Postmaster-General's Department in Queensland. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited up to June 1, for the supply of eight sections of common battery switchboard to the Postmaster-General's Department, New South Wales. Tender forms, specifications, and general conditions may be obtained at the Commonwealth offices, 72, Victoria-street, London, S.W. See also advertisement.

Tenders are invited up to June 8 for the supply of protectors, switchboards (small) and common battery telephones to the Postmaster-General's Department, Queensland. Tender forms, specifications and general conditions may be obtained at the Commonwealth offices, 72, Victoria-street, London, S.W. See also advertisement.

Littleborough Urban District Council invite tenders for the supply and laying of h.t. feeder cables, l.t. distributors, roadwork, &c., for private lighting, and transformer kiosk, with transformers and equipment and switchgear in substation. Copies of specification, forms of tender, &c., may be obtained from the clerk to the Council, Mr. Geo. H. Wild. The works are to be carried out in accordance with plans and specifications, which may be seen at, but not obtained from, the offices of the consulting engineers, Messrs. Hawtayne & Zeden, 9, Queen-street-place, London, E.C., from whom further information can be obtained. Tenders to the Clerk to the Council, Council Offices, Littleborough, near Manchester, by May 2.

Walthamstow Urban District Council invite tenders for the supply and erection of one feeder booster set, switchboard and accessories. Copies of specification, &c., from the electrical and tramways engineer (Mr. G. R. Spurr), Priory-avenue, Walthamstow. Tenders (by post only) to the clerk of the Council (Mr. C. Sydney Watson) by noon April 22.

Whitwood Urban Council invite tenders for copper cables, steel and wooden poles, supports, arms, insulators, &c., watertight street light fittings, meters, switchboard, instruments, &c. Specifications from Mr. H. Marsden, Electricity Works, Honley, and tenders to Mr. V. Hulme, County Chambers, Bradley-street, Castleford, Yorks., by April 28.

Grimsby Corporation invite tenders for supply of a small three-wire balancer for c.c. system, and two years' supply of c.c. motor-meters. Specifications from the borough electrical engineer, Mr. W. A. Vignoles, M.I.E.E., Electricity Works, Grimsby. Tenders by first post April 18.

Llandudno Urban Council invite tenders for replating batteries and supply of paper and vulcanised cable, feeder and distributing pillars, joint boxes, &c. Tenders to Clerk of Council by April 23.

Dartford Council require tenders by noon April 20 for supply of one feeder pillar and 900 yds. of 0·15 and 450 yds. of 0·07 paper-insulated lead-covered cable. Specification, &c., from the engineer.

The Deputy Postmaster-General, Melbourne, will receive tenders until 3 p.m. May 17 for supply of 1,010 reinforced concrete telegraph poles, preferably of Australian cement. Local representation necessary. Specification from Commonwealth office, London.

The Deputy Postmaster-General, Brisbane, will receive tenders until noon May 18 for 1,760 yds. of paper insulated lead-covered cable. Local representation necessary. Specifications from the Commonwealth office, London.

The Consejo de Administracion del Puerto de Montevideo (Uruguay) require tenders by 3 p.m. July 4 for supply of 20 electric cranes.

TENDERS RECEIVED AND ACCEPTED.

Keen competition for a contract for the supply to the Danish Government of submarine vessels in which European and American contractors were competing, has resulted in the contract being placed with Messrs. Whitehead & Co. (Ltd.), of Fiume, Hungary.

Sheffield Tramways committee has accepted the tender of Hadfield's Steel Foundry Co. for the manufacture, supply and delivery of special track work at £1,000, plus £213. 7s. 10d. for rails and fish-plates to be supplied by the Corporation.

Plymouth Town Council has accepted the tender of Willoughby Bros. for tramway blocks at 6s. 6d. per cwt., brake slides, 2d. each, steel slipper block bolts, 5d. each, and steel suspension bolts, 1s. 4d. each.

Sheffield Electricity committee have accepted the tender of the Electric Construction Co. for a rotary transformer and switchgear at £302. 15s. 10d.

Battersea (London) Council has accepted the tender of the General Electric Co. for annual supply of arc lamp carbons, and of Callender's Co. for annual supply of cables.

Digitized by Google

Warrington Council have accepted the tender of Chamberlain & Hookham for keeping the tramway meters in repair at 3s. 3d. per meter per annum.

The Clyde Navigation Trustees have accepted the tenders of Siemens Bros. Dynamo Works for additional generating plant at £6,442.

Tonbridge Council have placed an order with the British Thomson-Houston Co. for motor meters, with W. Geipel & Co. for carbons, and with the Western Electric Co. for cables for a year.

Colchester Corporation have accepted the tender of the Standard Cable Mfg. Co. for distributor cable at £242. 5s.

Bradford Corporation have accepted the tender of Thermit (Ltd.) for welding 600 tram-rail joints at £596.

Chester-le-Street Guardians have accepted the tender of G. H. Armstrong for an electric fan for the laundry at £27. 5s. 8d.

St. Helen's Council have accepted the tender of the British Insulated & Helsby Cables for cables.

Battery Contracts.—The storage battery at Rochester (Australia Commonwealth) central station, mentioned in our last week's edition was, we are informed, supplied by the D.P. Battery Co. through their local representative, Mr. T. K. Steanes.

The order for the large storage battery required by Guildford Electricity Supply Co. has been placed with the D.P. Battery Co., who have also undertaken its maintenance for 10 years.

Leek District Council and Letchworth Garden City, having found it necessary to enlarge their plant, have decided to adopt larger storage batteries, and have again placed orders with the D.P. Battery Co.

BUSINESS NOTICES.

Mr. J. E. Kingsbury has removed from Norfolk House, Victoria Embankment, to 7, Serjeant's Inn, Temple, London, E.C. Telegraphic address, "Rexinter London"; telephone 2418 Central.

The partnership between Wm. Taylor Thomson, Jas. Knox, Chas. Nugent Knox and Wm. Brown Macdonald (trading as Thomson, Knox Co.), electrical and mechanical engineers, &c., 10-12, Scrutton-street, Finsbury, London, E.C., 4, Marsden-square, Manchester, and 109, Argyle-street, Glasgow, has been dissolved. The business in Scotland and Ireland will be carried on by Mr. Thomson and the business in England by Mr. Jas. Knox, both trading under the style of Thomson, Knox & Co.

Robt. Arch. Dunt and Edwd. N. Bedells (trading as R. A. Dunt & Co.), electrical engineers, 91, High-street, Southampton, have dissolved partnership. Debts by Mr. Bedells, who continues as E. N. Bedells & Co., at 83, Above Bar, Southampton.

Electrical Engineering in Sweden.—The General Electric & Manufacturing Co. of Sweden (Allmana Svenska Elektriska Aktiebolaget) have recently opened offices at Norfolk House, Laurence Pountney-hill, Cannon-street, E.C., under the superintendence of Mr. S. H. Busch, who will act as representative in this country. An illustrated booklet issued on the occasion of the firm's 25th birthday gives a good idea of their activities. In this an interesting account of the work is to be found, while technical chapters on the "Development of Continuous-current Engineering" and "Switchboard Apparatus and Special Devices" are well worthy of study. A chapter on "Some of the installations and power schemes carried out by the Allmana Svenska Elektriska Aktiebolaget" contains details of power stations, rolling and paper mills and other applications of electrical machinery. Much of the plant now in use in Norway for producing nitrates from the atmosphere has been supplied by this firm.

For Sale.—In another column an electric light and power undertaking is advertised for sale as a going concern.

Factory Premises for Sale.—Mr. F. Warman, 52, Chancery-lane, London, W.C., has for sale some well-equipped factory premises in Reading. See an advertisement.

Telegraph Code Economiser.—Messrs. Sidgwick & Jacksou, of 3 Adam-street, Adelphi, London, W.C., have just issued, price 10s. 6d. net, a new and revised edition of Rose's "Universal Code Economiser," prepared by Mr. Sydney Rose, A.M.Inst.E.E., The "Economiser" is designed to work as an adjunct to all existing code books, and Mr. Rose claims that it is the only system by which a transposition error, of whatever magnitude, can be detected at sight, and rectified immediately by the recipient of the message. The fact that a new edition of this ingenious system has been called for indicates that code users, who are an increasing class, have found the method propounded by Mr. Rose of service. The bearing of such publications on the question of telegraph rates can perhaps be no more clearly shown than by a perusal of this work, which is a graphic example of the application of scientific treatment to everyday commercial transactions. In view of recent declarations as to the use of code vocabularies the new edition of Mr. Rose's "Economiser" is timely.

Osram Lamps for Ship Lighting.—Applied science has revolutionised ocean travel, and nowadays one is able to enjoy all the comforts of home life whilst travelling from continent to continent. Proper ventilation is secured by means of electric fans, heating by means of electric radiators; and clean, healthy and wholesome illumination by means of the electric light. For obvious reasons gas has never found a notch in the evolution of lighting on board ship, and it has been left to electricity to provide the long and keenly needed improvement in shipping illumination. Practically the whole of the large liners are now equipped with their own electric lighting plant, and the Osram metal filament lamp has come largely into favour on account of its remarkably long life and low current consumption. One of the White Star liners upon which Osram lamps are fitted throughout has just returned to port after a five months' cruise, and the engineer's report states that only one lamp has failed throughout the whole period of absence, although the average life of the lamps in question is already over 700 hours. We are informed that this liner is leaving for another cruise with identically the same lamps, and are taking only half the usual number of spares on account of the present perfect condition of the lamps now installed.

Welding of Rail Joints.—Thermit Limited are carrying out the welding of the joints in connection with the construction of an electric tramway in Edinburgh.

CATALOGUES, &c.

Combined Paper Knife and Bell Push.—A description of a useful piece of apparatus for the writing table is sent us by the General Electric Co. Its object is sufficiently explained by the accompanying illustration, which also shows the neat way the wires are led in so as not to interfere with the cutting part of the instrument. A further advantage is that, owing to the flex being always visible the paper knife cannot get lost under the documents on the desk, as so often happens with the ordinary type.

Dry Cells.—We have received from Messrs. Siemens Bros. & Co. copy of their latest catalogue dealing with dry cells and dry cell batteries, which supersedes the list of August last. It differs from the earlier list in certain minor respects, and information regarding ignition coils, suitable for use with Obach dry batteries is included.

We have also received from Messrs. Siemens two leaflets dealing respectively with bell wires and motor car leads. These are supplementary to their catalogue on vulcanised India rubber wires and cables.

"Venner" Time Switch.—We mean it to be a compliment when we say the most interesting part about the pamphlet recently issued by Venner & Co. dealing with their well-known time-switch is the way in which various well-known quotations have been adapted to what may be called electrical uses. There is, however, much useful information and diagrams anent the switch, whose advantages should certainly be considered by those who are likely to require time switches.

Switches.—We have received from Ernest F. Moy (Ltd.) a complete catalogue of their well-known switches. These cover a wide range and are easily adaptable for all kinds of electrical work.

Ediswan Specialities.—The Edison & Swan Company have ready a number of leaflets dealing with the numerous electrical articles turned out by them. These include combined switch sockets and plugs, instruments of various types, enclosed arc lamps and arc lamp accessories.

Installation News.—The current number of "Installation News" contains details of the new Simplex combined wall plug and lampholder adaptor, &c.

A.E.G. Zeitung.—The current number contains a well illustrated account of some electric pumping installations, and a hydro-electric scheme in Formosa is dealt with. An article by Mr. Forner gives some interesting details of the steam consumption of turbines, and there is a descriptive article on the harbour works at Constantza.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during March, 1910, and (*b*) during the current year from Jan. 1 to March 31, with the increases or decreases compared with the corresponding periods of 1909 :—

Electrical machinery (*a*) £54,275 (decrease £322), (*b*) £137,419 (increase £18,082); telegraph and telephone cables (*a*) £9,688 (decrease £275), (*b*) £37,178 (increase £12,373); telegraph and telephone appa-

Digitized by Google

ratus (*a*) £16,721 (decrease £2,863), (*b*) £41,901 (decrease £2,421); other electrical wires and cables, rubber insulated (*a*) £12,421 (increase £8,188), (*b*) £36,240 (increase £22,291); with other insulations (*a*) £2,728 (decrease £9,936), (*b*) £6,069 (decrease £23,819); carbons (*a*) £12,342 (increase £941), (*b*) £35,746 (decrease £432); glow lamps (*a*) £55,580 (increase £27,282), (*b*) £139,968 (increase £21,365); arc lamps and electric searchlights (*a*) £101 (decrease £214), (*b*) £1,276 (decrease £6,086); parts of arc lamps and searchlights (other than carbons) £4,995 (increase £533), (*b*) £17,374 (increase £5,011); primary and secondary batteries (*a*) £3,624 (decrease £767), (*b*) £9,457 (decrease £4,750). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £126,395 (increase £21,246), (*b*) £348,377 (increase £20,048).

Exports.—The exports of electrical machinery, material, &c. (*a*) during March, 1910, and (*b*) during the current year from Jan. 1 to March 31, and the increases and decreases compared with the corresponding periods of 1909, are as follows:—

Electrical machinery (*a*) £118,091 (increase £6,392), (*b*) £317,761 (decrease £16,837); telegraph and telephone cables (*a*) £640,004 (increase £594,878), (*b*) £743,240 (increase £644,996); telegraph and telephone apparatus (*a*) £12,221 (decrease £3,062), (*b*) £35,354 (decrease £14,596); other electrical wires and cables, rubber insulated (*a*) £23,788 (increase £2,079), (*b*) £98,197 (increase £35,582); with other insulations (*a*) £20,651 (increase £1,267), (*b*) £46,688 (decrease £13,218); carbons (*a*) £1,015 (increase £419), (*b*) £4,578 (increase £2,511); glow lamps (*a*) £10,720 (increase £3,328), (*b*) £31,830 (increase £14,421); arc lamps and searchlights (*a*) £1,529 (decrease £1,452), (*b*) £4,968 (decrease £1,121); parts of arc lamps and searchlights (other than carbons (*a*) £907 (decrease £1,454), (*b*) £3,518 (decrease £1,551); primary and secondary batteries (*a*) £6,042 (decrease £5,689), (*b*) £26,369 (decrease £4,064). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £758,160 (increase £597,516), (*b*) £1,110,996 (increase £687,512).

BANKRUPTCIES, LIQUIDATIONS, &c.

At Liverpool Bankruptcy Court on Monday, before Mr. Registrar Howarth, Mr. Alfred Horswell Gibbings, electrical engineer, of Gambier-terrace, Liverpool, appeared for public examination. The liabilities were returned at £2,784, assets £56.

Debtor stated that he had held successively the posts of electrical engineer to the Hove Commissioners, Hull and Bradford Corporations. He had also been chief engineer to the South Lancashire Tramways Co. and the Stalybridge, Hyde and Dukinfield Tramways & Electricity Board. He commenced practice in Liverpool in February, 1906, as a civil and electrical engineer, and until June, 1907, was in partnership with a Mr. Chauntler. In May, 1908, he made an agreement with the North British Electrical Power Synd. to act as consulting engineer in regard to some proposed works for the distribution of electrical energy in Scotland, from which very lucrative results were anticipated, with the prospect of developments on similar lines in Lanashire and the north of England. The intended operations were stopped, however, by sec. 23 of the Electric Lighting Act, 1909. That section had been inserted by the House of Lords on the third reading of the bill without any intimation or publicity being given. The effect of the section was to render it impossible for a private company or individual to supply electrical energy to customers in any area in competition with a local authority or other statutory undertaker without obtaining a provisional order. The cost of obtaining a provisional order, owing to the opposition to be expected and the probable restrictions that would be imposed, placed it out of the power of the syndicate to proceed. His agreement with them was, therefore, terminated, and a scheme which he had in hand in Yorkshire was similarly frustrated. He attributed his position entirely to the act in question.

An order was made for an amended deficiency account, and the examination was adjourned to May 9.

Hy. K. P. Berham (trading as the South of England Electrical Engineering Co.), 60, Fratton-road, Portsmouth, has been adjudicated bankrupt.

A dividend is to be paid to the creditors of Thos. Louis Callender (lately trading as the Shamrock Cycle Co.), electrical engineer, Grove-place, St. Helier's, Jersey. Claims to Mr. E. W. Humphreys, 4, Castle-place, Nottingham, by April 28.

Mr. Geo. E. Corfield, Balfour House, Finsbury-pavement, London, E.C. has been appointed trustee in the bankruptcy of Joseph Aug. Bauer (trading as the Electrical & General Engineering Co.), 17, Gracechurch-street, London, E.C.

The Contraflo Condenser Co. (Ltd.) and the Contraflo Continental Patents Co. (Ltd.) have passed and confirmed resolutions to wind up the respective companies, and to appoint Mr. Wm. S. Gregg (3 and 5, Crown-court, Old Broad-street, London, E.C.) liquidator with authority to consent to the registration of and enter into an agreement with the Contraflo Condenser and Kinetic Air Pump Co. (Ltd.)

A receiving order has been made against Wm. Hy. Palmer electrician, lately trading at 7, Gt. Castle-street, Oxford-street, London, W. The first meeting of creditors will take place on April 27, and the public examination on May 6, both at Bankruptcy-buildings, London, W.C.

COMPANIES' MEETINGS AND REPORTS.

BABCOCK & WILCOX (LTD.)—The net profit during the year ended Dec. 31 last was £360,003. 15s., which, with £43,278. 19s. 9d. brought forward, made £403,282. 14s. 9d. Deducting the interim dividends (paid in October) of 3 per cent. on the preference and of 8 per cent. on the ordinary shares (£69,400), the balance was £333,882. 14s. 9d. The directors recommend that the following dividends be paid for the half-year ended Dec. 31—viz., 3 per cent. on the preference shares, less tax (£3,000), and 8 per cent. on the ordinary shares, tax free (£66,400), and also a bonus of 8 per cent. on the ordinary shares, tax free (£66,400); also that £100,000 be placed to reserve, £25,000 to dividend equalisation fund, £10,000 to a staff pension fund, leaving a balance to be carried forward of £63,082. 14s. 9d. Although the sales during 1909 did not show much improvement compared with the previous year, the year's trading was beneficially affected by some older large contracts which during 1909 came into the accounts. The companies with which the company is connected gave increased returns. The cost of production of certain of their manufactures was also reduced during the year by improvements in machinery and organisation. Those factors having increased the profit as compared with last year, the directors consider that they are justified in suggesting the distribution out of the profits of 1909 of a somewhat larger bonus.

BROMLEY (KENT) ELECTRIC LIGHT & POWER CO. (LTD.)—During 1909 the lamp connections increased from 84,052 to 89,282 8 c.p., and notwithstanding the introduction of metal filament lamps the sale of current shows a slight increase. Including £296. 19s. 11d. forward, the profit was £12,196. 1s. 5d., and after payment of interest, &c., (£3,202. 10s.) the balance was £8,993. 11s. 5d. The directors recommend a dividend at the rate of 7 per cent. (making 5¼ per cent. for the year). £2,096. 4s. 4d. is placed to reserve for renewal of plant and £2,600 to general reserve, leaving £172. 7s. 1d. to be carried forward.

CALCUTTA TRAMWAYS CO. (LTD.)—The receipts during 1909 were £174,430 and working expenses £107,677, leaving £66,752, which, with £333 brought forward, makes £67,085. Interest and dividend on preference and ordinary shares paid absorbed £42,449, leaving £24,636. The directors propose payment of a final dividend of 2s. 6d. per share (making 4½ per cent. for the year), adding to depreciation £7,000 and carrying forward £435. The year's traffic receipts exceeded those of 1908 by £8,879, due in a great measure to extensions.

CANADIAN GENERAL ELECTRIC CO. (LTD.)—The report for the past year stated that, owing to financial and industrial depression, the first half of the year showed discouraging results. Fortunately, the latter part of the year showed such decided improvement that the directors almost succeeded in equalling the earnings of the previous year. At the time of closing the books there was more work in progress in various stages of completion than since 1907. Since the close of the year the marked improvement in volume of orders received had been maintained, and present trade conditions warrant the belief that the improvement will continue. Within the last two or three months the company had secured some of the most important contracts for electrical apparatus ever awarded in any country, totalling nearly 200,000 H.P., including three generators of 15,000 H.P. each, three generators of 12,500 H.P. each, and two of 11,000 H.P. each and for size and importance had no counterpart in the world to-day.

CITY (OF BRISBANE) ELECTRIC LIGHT CO. (LTD.)—During the half-year ended Jan. 31 the output was 1,066,088 units, against 976,786 for the corresponding period of 1908-9. The revenue from sale of electricity increased by 20 per cent. The credit balance was £4,456. 3s. 5d., which, with balance forward, made £5,860. 1s. 1d. Besides the preference dividend, a dividend at the rate of 8½ per cent. on the ordinary shares, and at the rate of 8¼ per cent. on the contributing shares were paid, together with a bonus at the rate of 2 per cent. on both the fully-paid ordinary and contributing shares. The balance (£1,950. 11s. 6d.) was carried forward. Good progress has been made with the new waterside power house, and the directors have ordered another 700 kw. turbo-generator, which, with the necessary boilers, pumps, &c., will, it is hoped, be ready for use early in 1911. The laying of mains in the City Valley area has made steady progress.

INDIAN ELECTRIC SUPPLY & TRACTION CO. (LTD.)—Mr. J. G. B. Stone, who presided at the meeting on Tuesday, said that the loss which had previously resulted from the working of the tramway had been eliminated and their business was gradually improving. Electricity supply for lighting and power for fans and other purposes showed an increase, and the returns received for this year also showed improvements in all directions.

INDO-EUROPEAN TELEGRAPH CO. (LTD)—The directors' report for the year ended Dec. 31 last states that the company's traffics show a steady increase and have been carried with gratifying accuracy and speed, to which the direct working between London and Karachi has contributed to a marked extent. The company's lines are maintained in the highest state of working efficiency, but it has nevertheless become evident that the constantly increasing traffics render imperative a permanent increase in the carrying capacity of the system, and the directors are taking active measures with that object. The chief difficulty with which the company has had to contend during the year has been the simultaneous lengthy interruption of both the cables across the North Sea, in which the company has leased wires. The question of additional cross-Channel cable accommodation is also receiving the close attention of the directors.

Digitized by Google

The revenue from message account and other sources amounts to £145,603. 17s. 5d., compared with £132,837. 4s. 4d. for 1908, an increase of £12,766. 13s. 1d. The expenses were, on commercial and general account, £49,386. 15s. 9d., and on maintenance account £28,909. 7s. 7d., total £78,296. 3s. 4d., against £75,733. 15s. 8d. for 1908, an increase of £2,562. 7s. 8d. After deduction of income tax paid and adding the balance from 1908, the available total is £70,478. 1s. 11d. Deducting interim dividend of £10,625 already paid, £59,853. 1s. 11d. remains for distribution. The directors now propose to declare a dividend for the six months ended Dec. 31, 1909, of 17s. 6d. per share (making with the interim dividend 6 per cent. for the year) and a bonus of 20s. per share, both tax free, and to make a special distribution of £12,750, equivalent to 15s. per share, out of interest upon certain investments and advance accounts. This distribution will also be tax free. They also propose to set aside £15,000 towards cost of increasing the carrying capacity of the system, and to hand over £5,000 further to the trustees of the retirement trust fund, carrying forward £7,978. 1s. 11d.

METROPOLITAN ELECTRIC TRAMWAYS (LTD.)—The total revenue for 1909 (including dividends from associated companies) amounted to £363,612. 16s. 6d. Traffic receipts (£326,441. 0s. 2d.) show an increase of £26,428. 7s. 9d. Deducting expenses, including £18,315 for reconstruction and renewals, and writing down preliminary expenses, &c., by £3,091, there remains £50,437. 9s. 11d., making, with £3,707. 8s. 3d. brought forward, a total of £54,144. 18s. 2d. The directors recommend that £6,000 be placed to reserve, that payment of the preference dividend (£25,000) be paid, and that an ordinary dividend of 5 per cent. (£19,566. 17s.) be declared, leaving £3,578. 1s. 2d. to be carried forward.

NORTH METROPOLITAN ELECTRIC POWER SUPPLY CO.—Revenue for 1909 amounted to £88,925. 8s. 11d., increase £14,051. 5s. over 1908, and expenditure was £44,504. 0s. 9d., an increase of £1,290. 18s. 4d. The balance of £44,421. 8s. 2d. at credit of net revenue account, together with interest receivable and amount brought forward, makes a total of £47,040. 0s. 8d. After providing for interest and transferring £2,000 to reserve for redemption of debentures, there remains £34,315. 6s. 3d. The directors recommend that £7,000 be placed to depreciation and £3,500 be written off preliminary expenses, &c. Cumulative preference dividend amounts to £1,976. 14s. 3d., and an ordinary dividend of 6 per cent. £21,001. 4s., leaving £837. 8s. to be carried forward. Capital expenditure during the year was £40,262. 12s. 8d., making £535,968. 5s. 9d. The total number of units sold during the year was 16,402,447, against 14,069,611, an increase of 2,332,836 (16·5 per cent.). Willesden Council have decided to continue to take from the company a supply of energy in bulk for seven years further from Februaly, 1911. The business of the North Metropolitan Electrical Power Distribution Co. (Ltd.) at Barnet, Enfield, Hertford and St. Albans continues to expand satisfactorily, the total connections to the mains at Dec. 31 being equivalent to approximately 61,450 30 watt lamps, compared with 45,200 at December, 1908. Four additional sections of light railway in Middlesex were opened for public traffic during the year, bringing the total length operated to 51¼ miles. The remaining 4¼ miles of the authorised light railways of Middlesex County Council are in course of construction, and will probably be completed before the end of 1910. The purchase of the portion of the Harrow-road tramway in London by London County Council was completed on Oct. 18 last. Since that date the company have continued to work the line under agreement. The extension of the tramway to Edgware-road is being constructed. The company holds 40,000 ordinary shares in the North Metropolitan Electric Power Supply Co., the revenue of which shows a satisfactory expansion, the number of units sold during the past year exceeding 16,000,000. The dividend receivable for 1909 amounts to £21,000 (6 per cent., against 5 per cent. for 1908).

SOUTH WALES ELECTRICAL POWER DISTRIBUTION CO. (LTD.)—The chairman (Mr. W. Gascoyne Dalziel) stated at the meeting on Tuesday that, owing to the closing of the Cwmbran station and the working of the Treforest station by the Treforest Company, their own company was for the first time in its history not making a yearly loss on working. During last year the Treforest Company's output had increased from 7,645,125 units in 1908 to 9,833,032 units in 1909, and the cost of generating had been considerably reduced. An additional 1,300 H.P. had been connected with the Treforest area, and the total now connected was 9,825 H.P. An agreement had been entered into with Caerphilly Council for the acquisition of their provisional order. The Treforest Company were considering an extension of plant.

WYCOMBE [(BOROUGH) ELECTRIC LIGHT & POWER CO. (LTD.)—At the meeting last week it was reported that during the past year the connections had risen from 49,648 to 51,025 8 c.p., an increase of 1,377 8 c.p. Including £77. 5s. 2d. brought forward, the profit was £4,900. 4s. 7d., and after paying interest (£3,017. 4s. 2d.) the balance was £1,883. 0s. 5d., out of which payment of a dividend of 2 per cent. for the year was authorised.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

STEPHEN COTTON & CO. (LTD.) (3,548.)—Reg. in Dublin March 20, capital £20,000 in £1 shares, to take over the business of iron and brass founder, electrical engineer, &c., carried on at Belfast, by Chas. C. Cotton under the style of Stephen & Co. Private company. First directors, C. C. Cotton, J. S. Cotton and H. C. Kennedy. Reg. office, Sidney-street West, Belfast.

A. DEAN & CO. (LTD.) (108,457.)—Reg. March 29, capital £1,000 in £1 shares, to carry on the business of electrical engineers, dealers in electrical fittings, cables, wires and sundries, contractors for electric installations, &c. Private company. First directors, A. Dean and Mrs. M. St. C. Dean. Reg. office, London House, London-road, Norbury, Surrey.

ELECTRICAL ADVERTISING CO. (LTD.) (108,465.)—Reg. March 29, capital £1,500 in £1 shares, to carry on the business of engineers, machinists, electricians, machine makers and dealers, &c. Private company.

FOSTER & PULLEN (LTD.) (108,579.)—Reg. April 4, capital £5,000 in £1 shares, to carry on the business of electricians, gas engineers, &c., and to acquire the business of lighting specialists, brassfounders, &c., carried on at Bradford. Private company. First directors, W. Grange (managing director and chairman), G. Grange and H. Pullen.

STATUTORY RETURNS.

ATLAS CARBON & BATTERY CO. (LTD.)—Return to Dec. 15 gives capital as £2,000 in £1 shares, all of which have been taken up. £8 has been received and £1,992 is considered as paid. Mortgages and charges, £3,000.

BUDE ELECTRIC SUPPLY CO. (LTD.)—In return to March 26 capital is £7,000 in £1 shares, of which 4,773 have been taken up. £4,769. 12s. 6d. has been received, leaving £4. 7s. 6d. in arrears. Mortgages and charges, £2,500 mortgage debentures.

CAMBRIDGE ELECTRIC TRAMWAYS SYND. (LTD.)—Return to Feb. 21 gives capital as £5,000 in £10 shares, of which 107 have been taken up. £9. 0s. 4½d. per share has been called up on 90, £10 per share on 10 and nil on 7 shares and £911. 12s. 1d. has been received. Mortgages and charges nil.

CHARING CROSS, WEST END & CITY ELECTRICITY SUPPLY CO. (LTD. According to return to March 17 capital is £2,100,000 in £5 shares (130,000 preferred, 130,000 ordinary, 80,000 City Undertaking ordinary and 80,000 City Undertaking preferred). 80,000 preferred, 80,000 ordinary, 80,000 City Undertaking preferred and 70,000 City Undertaking ordinary shares taken up. £5 per share called up on 80,000 preferred, 80,000 ordinary and 80,000 City Undertaking preferred. £1,200,000 paid. £350,000 considered as paid on 70,000 City Undertaking ordinary shares. Mortgages and charges, £1,045,735.

ELECTRIC WIRING & FITTINGS CO. (LTD.)—The capital in return to Feb. 16 is £5,000 in £1 shares. 1,382 shares taken up. £1,375 paid, leaving £7 in arrears. Mortgages and charges, nil.

WASTE HEAT & GAS ELECTRICAL GENERATING STATIONS (LTD.)—In return to March 14 capital is £250,000 in £1 shares. 150,000 shares taken up. £150,000 paid. Mortgages and charges, nil. Return of allotments made up to March 19 shows a further 10,000 shares allotted for cash.

MORTGAGES AND CHARGES.

SUNBEAM LAMP CO. (LTD.)—Issue on March 23 of £600 debentures, part of a series of which particulars have already been filed.

TRAFFORD POWER & LIGHT SUPPLY (1902) (LTD.)—Debenture, dated March 30, to secure £25,000, charged on company's undertaking and property, present and future, including uncalled capital (if any). Holders, W. T. Glover & Co.

VACTITE WIRE CO. (LTD.) - Particulars of £3,000 debentures created Nov. 18, but have been filed, the whole amount being now issued. Property charged, company's plant, fixtures, stock and other assets. No trustees.

CITY NOTES.

MEMORANDA (April 14).—**Bank rate 4 per cent.** (since February 17, 1910). **Price of silver,** 24⅝d. per oz. Consols 81⅛—81⅜ for money, and 81¼—81⅜ **for account. Consols Pay Day,** May 5; **Stock and Shares Continuation Day,** April 27; **Ticket Day,** April 28; **Pay Day,** April 29; **Mining Shares Carry Over Day,** April 26.

PRICES OF METALS (London).—*Copper*, cash, 57½; three months, 58¼. *Lead*, English, 12⅞—13¼; foreign, cash, 12¾—12½. *Spelter*, foreign, 22⅜—22⅝. *Tin*, English, 146½—148½; foreign, cash, 148¼—148½; three months, 150½—150½. *Iron*, Cleveland, cash, 51/1, and three months, 51/10.

BABCOCK & WILCOX (LTD.)—The directors have declared a dividend of 3s. 2½d. per share (tax free) on the ordinary shares, making 24 per cent. for the year 1909, compared with 20 per cent. for 1908.

CONSOLIDATED SIGNAL CO. (LTD.)—The directors have declared an interim dividend for the half-year to Feb. 16 of 6d. per share (tax free) on the ordinary shares.

CUBA SUBMARINE TELEGRAPH CO. (LTD.)—The directors have declared a dividend at the rate of 6 per cent. per annum.

DIRECT UNITED STATES CABLE CO. (LTD.)—The Board have resolved to pay an interim dividend of 4s. per share (tax free) (being at the rate of 4 per cent. per annum) for the quarter ended March 31 last, payable 25th inst.

FLEMING, BIRKBY & GOODALL (LTD.)—A dividend of 6 per cent. ha been declared.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have granted a quotation to $20,000,000 4½ per cent. funding and real estate mortgage 50 year gold bonds (due 1950) of the *Western Union Telegraph Co.* The committee have been asked to appoint a special settling day in and grant a quotation to a further issue of £2,500,000 4½ per cent. first and general mortgage 30 year bonds (London issue) of the *New York Telephone Co.*, and also to allow 600,000 £1 fully-paid ordinary shares of *Mather & Platt (Ltd.)* to be quoted.

NOTES.

The Institution of Electrical Engineers.

The following nominations for the new Council of the Institution of Electrical Engineers were announced at the meeting yesterday evening:—

President.

S. Z. de Ferranti.

Vice-Presidents.

W. H. Patchell. — W. Duddell, F.R.S.
J. H. Rider. — S. Evershed.

Members of Council.

H. Dickinson. — W. Judd.
J. E. Kingsbury. — Prof. T. Mather, F.R.S.
P. V. McMahon. — W. M. Morrison.
R. K. Morcom. — Major W. A. J. O'Meara, C.M.G
S. L. Pearce. — J. F. C. Snell.
W. W. Cook. — G. Stoney.
G. K. B. Elphinstone. — A. H. Walton.
C. H. Wordingham.

Associate Members of Council.

S. Morse. — E. Russell Clarke. — J. E. Taylor.

Hon. Treasurer.

Robert Hammond.

The names printed in italics are new nominations. The hon. treasurer retires annually, and is eligible for immediate re-election.

WE are sure that the nomination of Mr. FERRANTI as President will meet with unanimous approval, the only question that may arise being why this honour did not fall to his lot some years ago. His name was bound up with the industry in its early days, and those were days when problems of the greatest importance had to be solved with very little previous knowledge. The Deptford station, with its eight miles of high-tension transmission and special tubular mains, was regarded as a very doubtful experiment, and in the darkest days of the London Electric Supply Corporation young engineers used to travel to Deptford and view with wonder the castings of the (in those days) huge alternators, which, unfortunately, fate destined only for the scrap heap. It all seems very simple now, and what then appeared to be a mistake has turned out to be the right thing in the end. But Mr. FERRANTI, like many other men of note, was before his time, though we must confess this scarcely seems a good reason why he should be after his due time in filling the presidential chair of the Institution. Of the other new members, it may be said that they are all known to our readers as having attained to recognised positions in the electrical world or allied industries. Mr. PATCHELL and Mr. RIDER remain on the Council, but fill the more important positions of Vice-Presidents. We are glad to see the return of Mr. KINGSBURY, while Mr. MCMAHON, who has for so long been identified with the City & South London Railway, comes on as a new member. There is evidently a wish, which we think is highly desirable, to draw the local sections closer to the central body, for the remaining new members are chairmen, or past chairmen, of local sections, namely, Mr. DICKINSON, of Leeds, Mr. MORCOM, of Birmingham, and Mr. PEARCE, of Manchester. As an associate member of Council, Mr. MORSE once more places his legal and parliamentary knowledge at the service of the Institution.

The Westminster Street Lighting Contract.

THE proceedings at the meeting of the Westminster City Council, reported in our last issue, when the recommendations of the Works Committee regarding the renewal of the street lighting contracts were adopted, appear at first sight absolutely to rule out any claims that have ever been made on behalf of electricity for this purpose. Gas lighting is held up as being much cheaper in every way, while electric lighting is stated to be both expensive and of a disagreeable colour. When, however, we come to examine the question further we find that the Works Committee possess

Digitized by Google

in their chairman, Mr. JACQUES ABADY, a gentleman who is an out-and-out supporter of gas, and who lost no time in bringing before the meeting his own somewhat biased views on the subject. It is further apparent that the desire of a section of the Council was to rush the matter through in spite of the fact that the existing contracts, with a few exceptions, do not expire until next December.

THIS being the case, it was not altogether a surprise to find, on examining the contract figures, that it was proposed to supply and maintain the gas equipment at a price which seems rather "over-cheap." To take the 90 c.p. unit, the smallest for which a price was given, the Gas Light & Coke Co. offer to maintain a lamp of this power for a period of 15 years for a sum of £2. 12s. 6d. per annum (3,940 hours). Now, Mr. J. W. BRADLEY, city engineer of Westminster, as a result of tests made by him on the street lighting in Westminster (*see* THE ELECTRICIAN, March 11, 1910), showed that a gas lamp giving on an *average* 83 c.p. cost £1. 18s. 6d. per annum to maintain, exclusive of the cost of the illuminant. Taking this figure in the present instance, we find that a sum of 14s. per lamp per annum is left to pay for the gas. The type of lamp under consideration consumes, according to Mr. BRADLEY, 7·5 cubic ft. of gas per hour, so that the Gas Company are supplying gas for street lighting in this instance at a price of 5½d. per 1,000 cubic ft.—a rather different figure from the 2s. 10d. which the ordinary private consumer is charged, and from the 2s. 5d. which the City Council has been paying up to the present for practically the same lamps in Victoria-street. Even if the new conditions permitted a reduction in the amount of gas by one-third, and a corresponding increase in the price, the difference would still remain very large. Another point to notice in this connection is that to obtain the requisite 90 c.p. the Gas Company must use two mantles per lantern, unless, of course, they employ high pressures — an arrangement which is practically impossible, considering the relatively small units and the length of streets that have to be covered, and would at any rate mean an even greater cost.

WITH regard to the cost of maintaining high candle-power lamps, Mr. A. A. VOYSEY, electrical engineer to the City of London, showed that a 3,000 c.p. gas lamp cost the Corporation £46 per annum. The Gas Light & Coke Co. propose to maintain a similar lamp in Westminster for a sum of £20. 5s. per annum, gas being included in both cases. The discrepancy is somewhat large. In this connection it may be noted that the Gas Company will have some considerable difficulty in obtaining and maintaining a unit of 3,000 c.p. Even with the most modern arrangements they will probably have to erect three lanterns on one post for the purpose, the great amount of heat given out by large mantles making it impossible to use more than a certain number of mantles in one lantern.

ONE other point in connection with the financial side of the question may be noted. The prices given for the installation of the two systems of illuminants show a large sum in favour of gas. But it should be pointed out that this sum includes, in the case of electric light, the laying of long lengths of new mains, while in the case of gas the mains are already laid and their first cost has been paid off under the previous contract. The whole of the figures dealing with this subject given in the Committee's report are set out on another page of this issue and we recommend them to our readers as being of great interest.

WE cannot congratulate the Gas Company on the tactics they have adopted on this occasion. It is true that they would have lost heavily if the street lighting had gone out of their hands, for they possess little other load in Regent Street; but, on the other hand, this example of price-cutting will scarcely help them in their relations with the other metropolitan authorities. They have extensive contracts for street lighting with both the Paddington and Holborn Borough Councils, for which they are being paid on a considerably higher scale than 5½d. per 1,000 cubic ft., and these Councils will not unnaturally inquire why Westminster should receive preferential treatment. We are often informed by gas engineers that electric lighting authorities in charging a private consumer 5d. a unit and the street authorities 2d. a unit are doing the ratepayers grievous wrong. May we not point out that the Gas Light & Coke Co., in charging 2s. 10d. and 5½d. respectively are analogously doing their shareholders about 2½ times more damage, without, moreover, a legitimate reason for so doing, as questions of load factor do not arise. We cannot help feeling that the Gas Company has set itself too hard a task. Its request for the reduction of the penalty for not supplying the proper candle-power from 5s. to 6d. seems to show that it is not quite so confident as it should be of carrying out the terms of the contract. We should like, therefore, to see the whole matter more fully discussed than has been the case up to the present. The Westminster ratepayers are entitled, we agree, to obtain the cheapest and most efficient light, but it must be pointed out that to supply an article at 4d which cost 2s. to produce, is in the long run neither cheap nor efficient for any one concerned.

ONE point in conclusion, from the standpoint of the electrical industry. A contract of this kind is important because the result is accepted by the general public without inquiry into the reasons underlying the decision. If, in future, the tenders for London street lighting are to be put in by gas companies at unremunerative figures, and excessive price cutting is to be the order of the day, this fact should be clearly realised. The gas companies are at an advantage in the fight because they are not numerous and they each cover large areas; consequently, they can afford to enter into unremunerative contracts if such a policy seems desirable. Electric light undertakings are not in such a fortunate position, and the loss to any one undertaking might be serious. Under these circumstances is not combination possible? There is already a joint Publicity Committee. If it is essential, in the interests of the industry, that unremunerative public lighting be undertaken in certain areas, such as Regent Street, why should not the various electrical undertakings combine to share the loss? It is a case of advertising.

Railway Electrification in Chile.—It is reported by Reuter that the Chilian Government will, in May, ask for tenders for the electrification of the railway from Santiago to Valparaiso and its branches, the total length of line being 156 miles.

Cross-Channel Telephones.—In addition to the new London to Paris telephone cable to be shortly laid between Dover and Cape Grisnez, preparations are, it is announced, being made at Dover for laying an additional telephone cable across the Channel to Belgium, in order to connect up the principal centres of England beyond London with Brussels and Belgium. The Continental telephone cables have been so successful that the demand for their use has far exceeded anything which was anticipated. The new cable contains four lines giving two complete circuits, and will be laid between St. Margaret's Bay, Dover, and La Panne, near Ostend. There are now eight distinct telephone services, and they are quite unequal to the demand.

Industrial England in the Eighteenth Century.—On Wednesday last a Paper with this title was read at the Royal Society of Arts by Sir Henry Trueman Wood, secretary of the Society. The Paper dealt in some detail with the condition of the various industries then existing. In 1754 England was just ceasing to be an agricultural country, with no exports except raw materials, and no manufactures, and was preparing for the industrial revolution which in another half century transformed her into the workshop of the world. The change was due to the improvement of the steam engine at the hands of James Watt, and the consequent development of a great manufacturing system dependent on the motive power which could only be provided by steam. In the first half of the century spinning and weaving formed a bye-industry carried on by the country folk to supplement their agricultural earnings. In the second half, the textile manufacture had drifted into the cities, and was becoming the enormous industry it now is. In 1754 the iron manufacture was almost dead, because all the available wood had been turned into charcoal and used up. A few years later iron was being made with coal supplied in inexhaustible abundance from deep pits drained by the steam engine. Power provided iron and coal; iron supplied the material for new engines, and for machines to be driven by them, while the coal afforded a limitless source of power. Taking this main fact for his text, the author showed how the different industries of the country had been affected by the reciprocal influence of one upon another, and how their development had started from a point which might fairly be taken as coincident with the date of the foundation of the Society. It was, indeed, this sudden industrial development that led to the foundation of the Royal Society of Arts, the only one, among several started at the same time, which had lasted to the present day.

Determination of Depreciation.—Users of industrial plant and machinery are often at a loss to know what amount should be charged to profit and loss as depreciation, or loss of value caused by wear and tear, natural decay and obsolescence. Depreciation is one of the most difficult (and often one of the most neglected) questions connected with the ascertainment of annual profit, and there has hitherto been no recognised means of determining it in a scientific way. The appearance, therefore, of "Leake's Register of Industrial Plant" (London: Henry Good & Son, 12, Moorgate-street, E.C., price 5s. 4d., post free) for the classification of capital outlay and the measurement of depreciation, with introductory notes by Mr. P. D. Leake, F.C.A., is opportune. This register enables depreciation to be calculated on the original cost of each class of industrial plant, the calculation being based, as it should be, on the estimated efficient life periods, enabling revised estimates of these to be made and recorded at any time, and accounting effect being given to such changes. We note that the register for the first time makes possible continuous co-operation between engineers and accountants in this difficult problem, a point of great importance, especially in large works, where the accountants' rule-of-thumb method of calculating depreciation is not to the liking of engineers, who point out the impossibility of forecasting accurately the length of the efficient life of any kind of plant, in consequence of which it is necessary to revise original estimates as time goes on and more becomes known of the behaviour and prospects of the plant. It is proposed by Mr. Leake to leave this part of the work entirely to the engineers, whose written instructions in the register will be automatically acted upon by the accountants in measuring the annual depreciation necessary to be charged in the annual accounts.

The Comparative Effects of Protection and Free Trade upon the Electrical Industry.—We are informed that the National Electrical Manufacturers' Association will hold a meeting at Caxton Hall, Westminster, on Monday, May 23rd, at 8 p.m., when a discussion on this subject will be opened by Mr. Hugo Hirst from the Protection point of view, and Mr. J. E. Kingsbury from the Free Trade point of view. The chair will be taken by Mr. H. W. Butler, of the Electric Power Storage Co., the chairman of the Association. No resolution will be placed before the meeting or vote taken, and only those who are directly connected with the electrical industry will be allowed to take part in the discussion. Any person desiring to take part in the discussion is requested to send his name to the Secretary before May 21st. The Association does not hold itself responsible for the views expressed at the meeting. This action will doubtless be welcomed by many members of the profession

Cable Barge for Rio de Janeiro Bay.—The following particulars of a cable barge which is being supplied by Messrs. Siemens Bros. & Co. to the order of the Director-General of Telegraphs of Brazil, for the purpose of laying and repairing submarine cables in the Rio de Janeiro Bay, will be of interest to our readers. The principal dimensions of the barge, which is built of mild steel, are: Length between perpendiculars 90 ft., breadth moulded 20 ft., depth 6 ft. It will carry 150 tons on a 5 ft. draught. The barge will be fitted with a two-sheave bow-sheave, a combined picking-up and paying-out machine supplied with steam from a vertical boiler, and a cable tank 13 ft. 6 in. in diameter by 5 ft. deep, over which a curved sliding cover is arranged, thus allowing sufficient head room for the men in the tank and, at the same time, protecting the cable from the sun's rays. A testing room has also been built in the vessel's hold, with a skylight projecting through the deck, and she will further be equipped with a complete outfit of buoys, ropes, chains and the usual tools for jointing and splicing cables. At the forward end the plating has been carried up to form a support for the bow girders, and aft the deck is raised so as to enclose the boiler and stoking space as well as to form a platform for the helmsman, who will thus have an uninterrupted view of the entire length of the vessel. The maximum depth of water in which the barge is expected to effect repairs is 25 fathoms, and she has been designed to carry her full load of 150 tons on a draught of 5 ft. The vessel was launched on the 12th inst., is now being fitted with masts and sails, and, all being well, will proceed under sail and unaccompanied by any other vessel on or about May 1st for Rio. She has permanent sleeping accommodation for two hands, and temporary arrangements will be made for the remainder of the crew of about seven hands who will navigate this small vessel to the other side of the Atlantic.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

We publish an article giving interesting particulars of the progress made in street lighting by means of high candle-power metal filament lamps, more particularly at Wimbledon.

Mr. G. W. O. Howe contributes an article "On the Effect of Shunting Inductive Coils."

Before the Institution of Electrical Engineers last night a Paper was read by Mr. A. V. Clayton on "Hydro-Electric Installations in Sweden."

We give an account of the discussion which took place last week before the Illuminating Engineering Society on the subject of "Recent Developments in the Measurement of Light and Illumination."

Digitized by Google

An inquiry was held last week into the application of Ashton-under-Lyne Corporation for permission to borrow £48,424 for additional generating plant, &c.

Parliamentary.—On Wednesday Section B of the Local Legislation Committee of the House of Commons approved a proposal by Bradford Corporation to establish the railless trolley system of electric traction on one route.

Companies' Meetings.—At the recent meeting of the Pacific Oilfields (Ltd.), the chairman announced that, owing to the appearance of microscopic globules of water in the oil wells, they had decided to put down an electrical cleaning plant.

Mr. E. Garcke was able to make a very satisfactory statement as to the position of the Metropolitan Electric Tramways (Ltd.), and incidentally the North Metropolitan Power Co., at the meeting of the shareholders of the former undertaking last week. It also appears that the extensive network of tramways and light railways operated by the Metropolitan Electric Tramways is now completed, except for a few small linking-up lines.

INSTITUTIONS AND SOCIETIES.

Iron and Steel Institute.—The annual meeting of this Institute will take place on May 4 and 5 at the Institution of Civil Engineers, Great George-street, Westminster, under the presidency of the Duke of Devonshire. The Papers to be read will include, among others, the following: "On the Girod Furnace and the Electric Smelting Works of the Paul Girod System," by Prof. W. Borchers; "On the Progress of Electric Smelting," by Mr. D. F. Campbell, and "On Developments in the Production of Electric Power: Its Application and Bearing upon the Iron and Steel Industries," by Mr. D. Selby-Bigge. The annual dinner will be held at the Hotel Cecil on Wednesday, May 4th, at 7 p.m. The Great Western, the London & North Western, the Great Central, the Midland, the Great Northern, the North Eastern, the Great Eastern, the South Eastern & Chatham, the London & South Western and the Lancashire & Yorkshire Railway Companies, have arranged so that members attending the meeting can obtain a return ticket to London at the rate of a single fare and a quarter (minimum 1s.) on presentation of a voucher at the booking office of the station from which they travel. These tickets will be available from the day before, to the day after, the Meeting. The voucher will be supplied on application at the Institute offices. The autumn meeting will be held at Buxton on Tuesday, Wednesday and Thursday, September 27th, 28th and 29th. The morning sessions for the reading and discussion of Papers will be held, by kind permission of the municipal authorities, at the Pavilion, Buxton. An influential committee is in process of formation to carry out the necessary arrangements, of which due notice will be given to the members at a later date.

The Electric Sales Society.—We are informed that the staff of the Borough of St. Marylebone Electric Supply Department has formed a society with the above title for the furtherance of "business-getting" in connection with electricity supply. The Society meets every fortnight in the winter, and every month in the summer. At present the membership is confined to the staff of the St. Marylebone Electric Supply Department, but it is hoped in a short time to extend the scope of membership. Papers are given by experts on business-getting, points relating to electricity supply, electrical apparatus and work of all descriptions, particular attention being paid to all Papers concerning the commercial side of the question. The Papers given and discussion following will be printed for sale, and embodied in a monthly publication on electric sales work.

Royal Society.—Among the Papers read at the meeting of this Society yesterday afternoon was one on "The Total Ionisation produced in Different Gases by the Cathode Rays ejected by X-Rays," by Dr. R. D. Kleeman.

Institution of Mechanical Engineers.—The annual dinner was held on Thursday, April 14th, at the Hotel Cecil, the President of the Institution, Mr. J. A. F. Aspinall, being in the chair. Among those present were Sir Archibald Geikie, K.C.B., P.R.S., Sir David Gill, K.C.B., F.R.S., Surgeon-Gen. Sir Alfred Keogh, K.C.B., Sir Gerald A. Muntz, the Hon. Sir John W. Taverner, Mr. G. Lambert, M.P., Mr. A. H. D. R. Steel-Maitland, M.P., Col. H. C. L. Holden, F.R.S., Dr. Gisbert Kapp and Dr. R. T. Glazebrook, F.R.S. Mr. G. Lambert, in acknowledging the toast of the "Imperial Forces," proposed by Mr. J. R. Hoyle, remarked that the equipment of a modern battleship comprised, in addition to the main steam plant, 147 electrically-driven auxiliaries, 100 hydraulic machines, 96 auxiliary steam engines, 20 air-driven machines, and one oil engine, or a total of no less than 364 engines. It was evident from this how necessary to the Admiralty was the assistance of engineers. This toast was also acknowledged by Col. H. C. L. Holden. In responding to the toast of "The Institution of Mechanical Engineers," which was proposed by Mr. J. L. Griffiths, Consul-general of the United States, in an excellent speech, Mr. J. A. F. Aspinall queried whether we were represented abroad by the right kind of men to obtain for this country a fair share of the trade of the world. Scientific instruction in America and the eloquence of their consuls were abstracting our share of the world's work. Again, legislation considerably hampered railway enterprise in this country. In this connection he instanced the excessive cost of constructing light railways in the United Kingdom compared with the cost in Belgium, which latter country possesses about 5,000 miles of railways, some 2,500 miles being classed as light railways and having been constructed at a cost of about £3,400 per mile. By extending our railways we might develop our industries and so prevent, to some extent, the importation of manufactured articles. The toast of "Our Guests" was proposed by the President, Sir John Taverner responding.

ARRANGEMENTS FOR THE WEEK

FRIDAY, April 22nd (to-day).

Physical Society.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. Agenda: "Further Tests of Brittle Materials under Combined Stress," by Mr. W. A. Scoble, and "The Magnetic Balance of Curie and Cheneveau," by Messrs. C. Cheneveau and A. C. Jolley.

Royal Institution.

9 p.m. Meeting at Albemarle-street, Piccadilly, W. Discourse on "The Telegraphy of Photographs, Wireless and by Wire," by Mr. T. Thorne Baker.

MONDAY, April 25th.

Newcastle Local Section of the Institution of Electrical Engineers.

8 p.m. Meeting in the Armstrong College, Newcastle-on-Tyne. Paper on "Earthed *versus* Insulated Neutrals in Colliery Installations," by Mr. W. W. Wood.

TUESDAY, April 26th.

The Institution of Civil Engineers.

8 p.m. Annual General Meeting at Great George-street, Westminster, S.W.

Faraday Society.

8 p.m. Meeting at the Institution of Electrical Engineers, 92, Victoria-street. General discussion on "The Constitution of Water." Papers on "Is Water an Electrolyte?" by Prof. P. Walden; "The Nature of Molecular Association in the Special Case of Water," by Prof. P. Guye; "Liquid Water as a Ternary Mixture, Solution-Volumes in Aqueous Solutions," by Mr. W. R. Bousfield and Dr. T. M. Lowry; and "The Specific Heat of Gaseous, Solid and Fluid Water," by Mr. W. Sutherland and by Prof. N. Nernst.

WEDNESDAY, April 27th.

Birmingham Local Section of the Institution of Electrical Engineers.

7:30 p.m. Meeting in the Chemical Theatre, The University Edmund-street. Paper on "Magnetic Oscillations Occurring in D.C. Machines," by Mr. G. W. Worrall.

Students' Section of the Institution of Electrical Engineers.

7:45 p.m. Meeting at 92, Victoria-street, S.W. Paper on "Some Notes on Current Central Station Design in Germany," by Mr. J. C. Connan.

THURSDAY, April 28th.

The Institution of Electrical Engineers.

8 p.m. Meeting at the Institution of Civil Engineers, Great George-street, Westminster, S.W. Paper on "Earthed *versus* Insulated Neutrals in Colliery Installations," by Mr. W. W. Wood.

FRIDAY, April 29th.

Students' Section of the Institution of Civil Engineers. Visit to Southampton Docks, and to Messrs. Harland & Wolff's Engineering Shops.

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. B. Crompton, C.B.

The following orders have been issued for the current week:—

Monday, April 25th, "A" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 9:30 p.m.

Tuesday, April 26th, "B" Company.—Infantry Drill, 7 to 8 p.m. Technical Drill, 8 to 10 p.m.

Wednesday, April 27th.—Gymnasium, 6 to 9:30 p.m.

Thursday, April 28th, "C" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 8 p.m. Technical Drill, 8 to 9:30 p.m.

Friday, April 29th, "D" Company.—Company Drill, 7:15 to 8:30 p.m. Technical Drill, 8:45 to 9:45 p.m.

Saturday, April 30th, "A" and "B" Companies.—Company Drill, 3:30 to 5 p.m. "C" Company.—Company Drill, 3 to 4:30 p.m.

HYDRO-ELECTRIC INSTALLATIONS OF SWEDEN.*

BY A. V. CLAYTON.

Summary.—After drawing attention to the characteristics of Sweden the author refers to the development of power transmission in that country. He then proceeds to describe typical installations, mentioning the features of particular interest.

It is impossible within the scope of this Paper to do more than briefly describe a very small number of the hydro-electric installations of Sweden, but before proceeding with the principal subject it may not be amiss to describe shortly the characteristics of the country, of which many people have only a very hazy knowledge. The length of Sweden is 986 miles, or nearly three times the length of England. Its area is 170,713 square miles, or about three times that of England and Wales together. The population is 5,377,713, or 32 inhabitants per square mile, so it will be seen that it is very sparsely inhabited compared with the 500 inhabitants per square mile of England and Wales. The population of Sweden is more dense in the South, where in one county it goes up to 240 per square mile, while in the North it is only 2·6. It seems remarkable that a country having such a small population should be able to supply itself with all its wants, and in many industries even a considerable export trade has been built up. The country is very hilly, abounding in lakes and watercourses, and the falls on these waterways have made it a busy hive for the electrical industry since the commercial development of electrical power transmission. At the same time, it may be stated that the present flourishing condition of many Scandinavian industries is due to the successful commercial development of electricity, whereby cheap power has become generally available. The area of lakes in Sweden is 13,900 square miles, and from this some idea of the enormous quantities of water available will be gleaned. My colleague, Lieutenant Lubeck, has estimated that the amount of water power available in Sweden is equivalent to 3,800,000 H.P. Of this only 550,000 H.P. is at present harnessed, so that there is plenty of scope for further development. That the equipment of the falls is proceeding very rapidly, however, may be gathered from the fact that in 1900 only 253,000 H.P. was utilised, or less than half of what is now employed. In the neighbouring country, Norway, there is available 4,800,000 H.P., of which in 1906 only 250,000 H.P. was utilised. However, since the advent in the last few years of new electrical processes for the production of fertilisers from the air, considerable additions have been made to this figure, so that now the falls harnessed, or in course of being harnessed, represent approximately 550,000 H.P., or about the same as Sweden.

The use of water power dates back to the very earliest ages; and there may still be seen in many places good examples of old-world water-wheels. These wheels were used for a variety of purposes, such as grinding mills or pumps, and very largely for ironworks. With the growth of the ironworks and the introduction of rolling mills, for which larger powers were required than could be obtained from the individual local falls on which the works were situated, a demand grew up for power transmission in order to bring the power from falls situated a little higher up or lower down the watercourses, and concentrate all to the point where the works were situated. This demand for power transmission was in part filled by wire-rope transmission, and some good examples still exist. Another system of transmitting power which is of much earlier date than wire-rope transmission consists of a number of wooden beams linked together at the ends and supported at intervals clear of the ground. These linked beams are placed in two parallel lines about 4 yds. or 5 yds. apart, and the cantilever supports, which hold them about 4 ft. from the ground, are hinged so as to allow them to be freely pushed or pulled longitudinally. To the ends of each line of these linked beams are attached a pair of connecting rods from cranks on the water-wheel shaft which give a slow reciprocatory motion to the links; one side of the line thrusting, while the other pulls. These transmissions were very widely used for mine pumps and for blast furnace blowers, in which cases the slow reciprocatory motion was very suitable for use at the receiving end of the line, as it was not necessary to reconvert to a rotatory motion. Some of them were quite long, and their efficiency is claimed to be very good.

With the advent of electricity a new era began, and between the years 1885 and 1889 power transmission by this means was touched on slightly. It was not, however, until the invention of the three-phase system that any real advance was made. The first three-phase transmission in Sweden was tried in 1890, and in 1893 a transmission on what was for that time quite a large scale was inaugurated. This was of 400 H.P. capacity, and the power was sent from the Hellsjon falls to the Grangesberg iron mines—a distance of about 10 English miles. The original plant consisted of four water-turbine driven generators, each of 100 H.P. Three of these are of three-phase design and supply power to the pumps, haulage gears, hoists, and other machinery at the mines, while the fourth is a single-phase generator for lighting purposes. All operate at 70 cycles, and run at 600 revs. per min. Current is generated at low voltage and transformed up to about 9,000 volts for the line transmission. The generators are of the rotating armature type, having inwardly projecting field poles, and the carcase, or yoke and poles, are of cast iron. This type of machine, while it presents some advantages, has been abandoned in favour of the rotary field type, except in the very smallest sizes. The General Electric & Mtg. Co., of Sweden, carried out the installation, and it may be mentioned that the original machinery is still at work 24 hours daily. As illustrative of the enormous development of the use of electrical power, it may be noted that the Grangesberg mines now employ about 6,100 H.P. electrically, and on account of scarcity of power have recently acquired new waterfalls of about 15,000 H.P., and the work of harnessing these electrically is at present in progress.

Alby.—Alby has been chosen among the power stations to be described on account of its having been partly acquired by English capital, and the name may be familiar to many. It is one of the older power stations, and was built in 1898-1899. The power from the Alby falls (which are situated on the Ljungan river) is used partly for the production of calcium carbide and partly for the manufacture of potassium chlorate. The original power plant consisted of two generators of 1,100 H.P. each, generating direct current at 220 volts for the manufacture of the chlorate by electrolysis; one two-phase 26 cycle 2,000 H.P. generator and two 500 H.P. single-phase generators for carbide production; besides two 360 H.P. continuous-current generators for excitation. All these machines are direct driven from horizontal shaft turbines. A few years later the power station was extended by erecting another 1,100 H.P. direct-current generator for chlorate manufacture, and another 2,000 H.P. two-phase generator for carbide. With the addition of some smaller sets for driving light railways, and some auxiliary machinery for making packing barrels, boxes, &c., these extensions brought up the total power installed at Alby to its present figure—9,760 H.P. The current from the 2,000 H.P. two-phase generators is delivered at 2,000 volts, and is transformed to the voltage required for the carbide furnaces by transformers situated immediately behind the furnaces. 1,000 H.P. is required for each of the larger furnaces, each phase of the two-phase generator supplying a furnace, while the 500 H.P. generators are of low-voltage type, work in parallel, and supply three smaller furnaces directly. In 1906 the carbide works were still further enlarged, and the power for these extensions is supplied from falls lower down the river at Ringdalen, about 1½ miles from Alby, and is transmitted at 10,000 volts.

As to the construction of the power plant, the first portion of the water intake canal is built of ordinary earthwork, and the latter portion near the power house end is constructed of stone masonry, the fall at this point being too high for earthworks. The total length of the canal is 700 yds., of which 170 yds. are built of masonry, and there are no less than 280,000 cubic ft. of stonework in it. The velocity of the water in the earthwork part of the canal is 1 ft. per second, while in the stone part it is 1·6 ft. In constructing the earthworks of the canal a sponting or core of tongued and grooved planking has been left in the middle of the earthworks to prevent percolation. From the end of the canal where it opens out into a large basin or settling pond, tubes of wrought iron convey the water directly to the turbines, which are situated in the power-house itself. There are seven tubes, five of these are 6 ft. diameter, and two are 8 ft. diameter. Of the five smaller tubes, three supply the turbines of the 1,000 H.P. direct-current generators, and two the turbines of the 500 H.P. alternators and exciters. The remaining two large tubes supply the turbines of the 2,000 H.P. two-phase generators. The length of these tubes is 72 ft. and the velocity of water in them is 5·5 ft. per second. The turbines work under a head of 69 ft. to 75 ft., of which 15 ft. is obtained from the suction draft tubes, the turbines being placed in flumes on the machinery hall floor, above the tail race level. The length of the tail race is 160 yds., and the velocity of water in it from 2·3 ft. to 3·3 ft. per second. The base of the power house is built of concrete, the station floor on which the turbines and generators are situated being supported on arches which form separated chambers for the water discharge from the turbines. The machinery in the power house cannot be considered as an example of good modern practice. The outer cases of flumes of the turbines were made of cast iron, a practice now abandoned for large-sized modern turbines. On one occasion, one of the outer cases burst owing to a flaw in the casting.

causing much damage to the station and loss of life, before the water at the inlet gates could be shut off.

Ringdalen.—The newer power station at Ringdalen also supplies power to the Alby carbide works. The fall is 52 ft., and in the power station are five 1,100 H.P. single-phase generators, one 600 H.P. three-phase generator for supplying motor and lighting load, and two 200 H.P. exciters. All the generators supply at 10,000 volts, at which pressure the power is transmitted to Alby. Each 1,100 H.P. generator supplies one carbide furnace and has its own transmission line with step-down transformers, so that they form five complete separate and independent units. All the generators are driven by direct-coupled single-wheel turbines. The length of the water intake canal is 450 yds., and the speed of the water in it is 1 ft. per second. There are six iron tubes to convey the water from the settling pond down to the turbines, one each for the five 1,100 H.P. three-phase generators and the two exciters. All the tubes are 6½ ft. diameter. The power station is built much on the same lines as that at Alby, but is more modern in its arrangements in the machinery hall.

Gullspang.—The power station at Gullspang possesses several points of interest. It is in the southern part of Sweden, and the falls are situated on a short river between the lakes of Skagen and Vänern. The falls are now owned by the Gullspang-Munkfors Power Supply Co. The power is transmitted at 40,000 volts, and

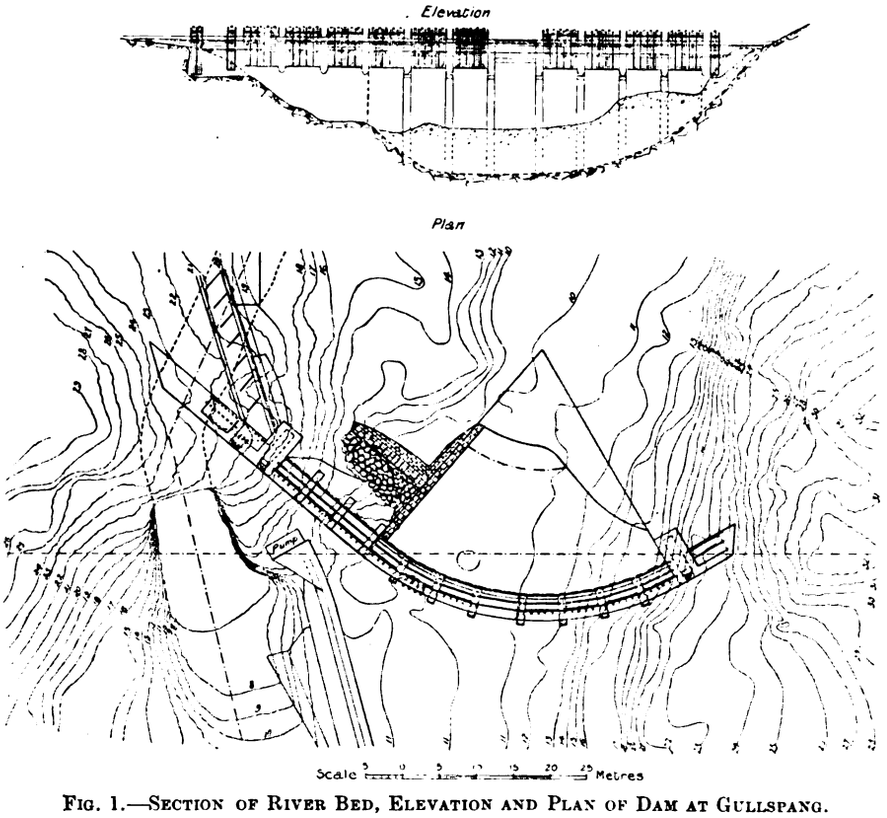

FIG. 1.—SECTION OF RIVER BED, ELEVATION AND PLAN OF DAM AT GULLSPANG.

the greatest distance to which it is at present delivered is about 50 English miles. Lake Skagen has an area of 50 square miles, and forms an ideal natural storage for the water supply, allowing of regulation for the wet and dry seasons. The mean water flow at Gullspang for high and low-water periods is about 2,550 cubic ft. per second. The distance by land from Lake Skagen to Lake Vänern is at one point only 1¼ miles, but the length of the river connecting the lakes, and upon which the Gullspang power station is situated, is 8 miles. In its course are two falls, or, more strictly speaking, rapids, namely, Gullspang Rapids, having a fall of 67 ft. in a distance of about ½ mile, and Aras Falls, of about 10 ft. It is intended eventually to utilise the second falls at Aras by deepening out the tail race from Gullspang down to Aras. At the point where the power station is situated the river runs through steep walls of rock, and in order to build a dam across the stream, the water had to be diverted from its natural course through a temporary tunnel blasted through the rock. This was, of course, a very costly proceeding, but under the peculiar circumstances no other way of doing the work satisfactorily was possible. This tunnel was about 60 yds. long and 30 ft. diameter. When the river bed was laid dry it was found not, as had been expected, to consist entirely of rock, but that to get to the solid rock considerable and expensive excavation would be necessary. The original plan of building a gravity dam straight across and supporting it on the solid rock bed was therefore abandoned, and, instead, an arch-formed dam was built on that portion of the river where the solid rock could not be got to without excavation.

Fig. 1 shows a section of the stream bed and plan of the dam. The straight part of the dam constructed on the gravity principle, and resting on the solid rock bed, was brought out as far as possible. The arch part of the dam has the crown of the arch, as it were, against the stream or head of water and the arch buttressed or wedged in between the solidly supported ends. By employing this means of construction an enormous saving both in the cost of excavation and of material employed was effected. The front of the dam is faced off with cement, and the bottom caulked with stamped clay to prevent leakage. Fifty regulating sluices are provided, grouped in 10 openings of five sluices each. The sluices are of wood, working in I-section steel girder frames. A large opening or spillway in the centre of the weir is provided for clearing off loose ice. A salmon pass and two eel passes are, as is usual, also provided. The water is led from the head race to the turbine house in an open canal. The bottom part of this canal has for a great part of the way been blasted out of rock and is built with concrete walls, while the upper part consists of earthworks. Where the junction between the concrete walls and the earthworks is made, a sponting of concrete prevents leakages, and the earthworks are for part of the way constructed with wood sponting, as in the case of the Alby canal.

The power station proper and the forebays are built close together. Fig. 2 shows a section of a forebay with ice racks, sluices, turbine flume, turbines with draft tube, tail race, tunnel, and power house. The forebays are built of reinforced concrete, and the power station partly of concrete and partly of brick. The turbines are of twin type, and are placed in open vertical tubes or flumes of boiler plate. These flumes are 43 ft. long and 18 ft. diameter. When completed, there will be six turbine flumes, each constructed for a pair of 4,500-5,000 H.P. turbines for driving the main generators, beside the auxiliary turbines for the exciters. Only four pairs of turbines and generators with exciters are installed at present, the remaining two being reserved for extensions. Each of these turbine flumes is separate in itself, and provided with its own forebay, ice rack and head gate. The head-gates are 18 ft. wide and 15 ft. high, and are of an interesting and novel construction, for which patents have been applied for. They consist of cylindrically bent iron plates stayed with horizontal struts, and are provided with oak sliding surfaces. As these gates are too wide to be manœuvred against the water pressure, by-passes are arranged to fill the forebays previous to operating the gates. The gates themselves are raised or lowered by a travelling crane, which can be moved over each sluice. Each of the forebays stands for itself; they are not connected to each other, and are free from the rock at the sides, being supported solely from the bottom on concrete walls which stand up between the turbine flumes. The joints between the boiler plate turbine flumes and the concrete floor of the forebays are of expansion type. In order to effect this each flume tube was well greased before the concrete was stamped in round it, while to ensure a watertight joint between the concrete and the tube, a V-shaped groove was left round the top of the tube in the concrete, and into this groove a packing of tow steeped in paraffin wax was inserted. The pressure of the water forces this wedge-shaped tow packing ring in against the tube, just in the same way as in an ordinary hydraulic ram joint, and makes a perfectly tight joint. The backs of the forebays are made of thin half-circle walls, while the sides are of heavy straight construction.

The turbines, with their supply tubes and draft tubes, as well as the concrete walls supporting the forebays, rest on a floor of massive steel girders and reinforced concrete, which is built on the solid rock. This floor is of immensely strong construction, as it has to carry not only the weight of the turbine chambers, &c., but also the volume of water in them. The draft tubes have cement coatings to protect them from rust, and discharge into a tunnel, blasted out of the rock, running lengthwise under the power station. Further down the discharge tunnel opens out into an ordinary open tail race.

The power house building itself is in three storeys, and is built on the solid rock, which has been blasted out to a depth of 33 ft. to

Digitized by Google

accommodate it. The lower story is constructed of armoured concrete, with a view to better resistance to the damp from the adjacent rock; and, further, the walls of this chamber had to be of great strength in order to support the heavy transformers situated on the iron girder and concrete floor of the second story. The upper portion of the building is of brick. In the bottom story the generators are situated. On the first floor are the transformers and switchgear, while the top is devoted to the lightning protection devices and outgoing lines. The first floor is level with the ground outside, and on this floor run rails connected with a siding on the main railway lines. A 20-ton electric crane can take goods off the railway trucks and deliver them on to this floor, or drop them through an opening into the machinery hall below, which is served with another 20-ton electric travelling crane. A very complete system of ventilation has been arranged to keep the machinery hall cool, and there are channels running under the floor connected with the generator pits to conduct cool air to the generators.

The runners of the turbines are made with boiler-plate buckets, bent to the correct shape and cast into a cast-iron hub and ring.

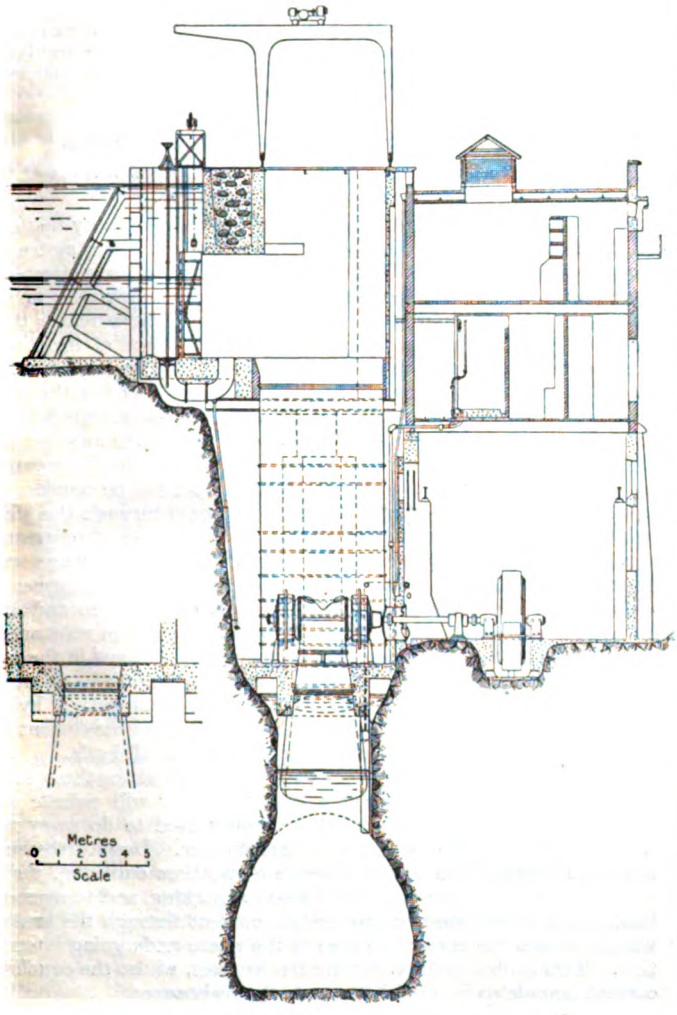

Fig. 2.—Section of Power Station at Gullspång.

This method ensures a smooth and even bucket, which minimises skin friction, and so improves the efficiency, and at the same time the bucket is stronger and less likely to be damaged by sticks, stones, ice or rubbish which may get in, than is a cast-iron bucket. This style of making runners is much employed for turbines working on falls up to about 65 ft., and up to sizes about as large as these—*i.e.*, 2,000 to 2,500 H.P. per wheel. For larger sizes and bigger falls cast-steel runners should be used. The guides or chutes leading the water into the wheel are movable on pivots, and by the movement of these chutes the openings between them are varied, and the amount of water admitted is regulated to suit the power required. This method of regulation ensures the water being always projected at the correct angle to the wheel buckets, and improves the efficiency at light load enormously. Fig. 3 gives the efficiency test curve of the turbines. Regulation of speed is effected by automatic hydraulic regulators operating directly on the shafts connected to the links of the afore-mentioned movable chutes. The governor balls are driven from the turbine shaft. They control a little valve, and in rising or falling with variations of speed admit water into either end of a cylinder. The piston in this cylinder operates, through a rack and segment gear, the shaft connected with the movable chutes. Speed regulation with regulators of this class is exceedingly sensitive. Tachograph records taken on the Gullspang turbines show that with the instantaneous application of full load to the turbine running light, or the throwing off of full load, there is a variation of only 5½ per cent. in speed; while for load variations of half or full load the speed varies only 2 per cent., and, what is still more important, there is absolutely no hunting even with these large changes of load.

The machinery in these power stations is much alike, and therefore the electrical plant in one station may be taken as typical of all. The chief interest centres about the hydraulic constructions and general layout of the installations. Before leaving Gullspang, however, there is just one point, namely, that of the cost of the equipment. At the present time there is installed machinery aggregating 16,500 H.P. exclusive of excitation, and this has been erected at a total cost of £173,000, or about £10. 10s., per horse-power. It must be remembered, however, that the hydraulic part of the scheme has been calculated for an equipment when completed of 25,000 H.P., and in order to carry out this extension there is little expense to be incurred beyond the cost of the machinery. Therefore, when completed for its full capacity of 25,000 H.P., the power station will cost £192,000, or about £7. 15s. per horse-power. The Hydraulic Association of Scandinavia, or "Vattenbyggnadsbyran," was retained as the consulting firm for the scheme, and not only prepared the plans, but supervised the carrying out of the entire work.

Graninge.—In the north of Sweden, at Graninge, a new power station has been completed which deserves notice. This station is built for a capacity of 10,000 H.P., of which 5,000 H.P. is now installed and at work. The units are each of 2,500 H.P. capacity, running at 300 revs. per min., and generate at 5,000 volts, at which pressure part of the power is used in the immediate neighbourhood, while the

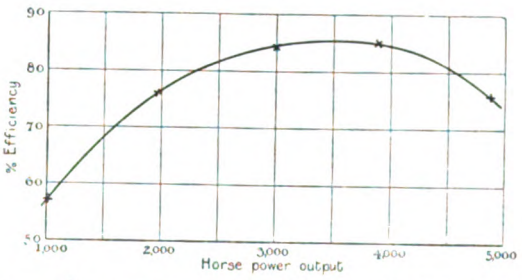

Fig. 3. Gullspång Efficiency Test Curve of 4,500 H.P. Turbines.

remainder is transformed up to 40,000 volts for the long-distance transmission. Fig. 4 shows a sectional elevation of the power house. There are not separate feeder tubes for each turbine, but three tubes lead into a common header from which the four turbines are fed. In addition to the gates on the turbines themselves, there are throttle-valve sluices between the turbine flumes and this common header. As regards the electrical outlay of the power station, all the low-voltage or 5,000 volt 'busbars, apparatus, and outgoing lines have been kept on one side of the building, and all the high-tension 40,000-volt apparatus on the other. The turbines operate under a 60 ft. head, and consist of twin wheels mounted on horizontal shafts. Each pair of wheels is mounted in a steel flume, and the discharge is through cast-iron quarter-turn discharge pipes and draft tubes, each discharge pipe and draft tube being common to a pair of twin wheels. As the flywheel effect of the generators is not in itself sufficient to enable the fulfilment of the speed regulation required, heavy flywheels are placed between the turbines and the generators. These flywheels have their own bearings, and are connected through leather band flexible couplings to the turbines, and through fast flange couplings to the generators. Governors of the type previously described are provided, and on test the speed variation was found to be 2½ per cent. for sudden variations of load equal to 20 per cent. of full load.

The three-phase generators are of 2,150 kw. capacity each, 50 cycle, 20 pole, 300 revs. per min., and generate at 5,000 volts. Their tested efficiency is 95·4 per cent. on full load of unity power factor, and 94·2 per cent. on full load of power factor 0·8. The inherent regulation is 1·5 per cent. for unity power factor, and 6·3 for power factor 0·8. It will be remarked that this inherent regulation is very good, but in general the regulation of generators employed in Sweden is not nearly so good, 7 per cent. and 16 per cent. being the more usual figures. The rotating magnet wheel with poles, arms and boss is in one single steel casting, and the pole shoes are of forged steel screwed

Digitized by Google

to the poles with countersunk bolts. The flanges formed by the pole shoes hold the field spools in place. The stator winding consists of bars, one in each slot, and the slots are partially closed. The stator frame with punchings is in halves, and one of the feet on which the frame rests is bolted to the frame. By removing this loose foot the whole stator can be let down on to the field, and so turned round on the shaft to bring any part of the windings situated below the ground level into a convenient situation for inspection or repairs. The bearings are of the ordinary spherical seated self-aligning type, with babbit linings and ring lubrication.

Almost all the Scandinavian hydraulic power stations are employed for power transmission, hence they nearly all employ three-phase generators, and the generators described may be taken as typical of the general run of plant in Scandinavian hydraulic power stations. With the exception of a few electrochemical works, where low-frequency is necessary, 50 cycles has generally been accepted as the standard. The new State power scheme at Trollhättan is, however, designed for 25 cycles, partly with a view to the use of the power for railways. The City of Stockholm primary transmission is also at 25 cycles, but with these exceptions it may be said that for supply companies 50-cycle three-phase is universal. This is a very great convenience, as it simplifies matters and standardises plant considerably.

Four interesting generators, of 10,500 kw. capacity, 10,000 volts, 50 cycles, and 250 revs. per min., have been supplied by the General Electric & Mfg. Co. of Sweden to the Notoddens Saltpetre Works at Svälgfos in Norway. In this generator the steel poles and ring are

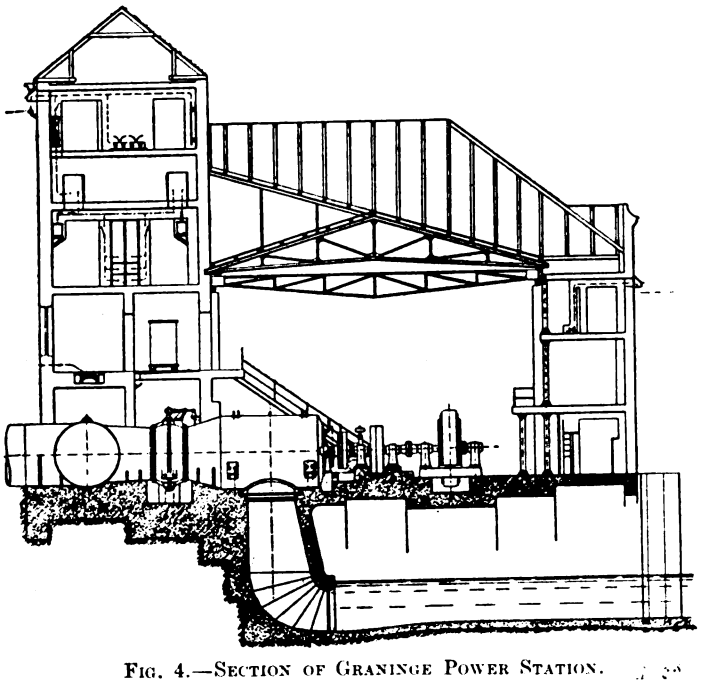

Fig. 4.—Section of Graninge Power Station.

cast together, and are supported on a cast-iron arm system. The magnet ring and poles are divided transversely, and an air duct is left between the halves. The width of iron axially in this machine is no less than 49 in., the bearings are of ring lubrication type, and are provided with water cooling in case it ever be required.

These enormous generators have been quite eclipsed in point of size by other generators which the same Company are building for the above-mentioned Trollhättan State power scheme. These are of 12,500 k.v.a. output, and recently the Company has received orders for generators for Rjukanfos, which are of 14,500 k.v.a. capacity. There are two unique generators, built and designed by the same Company, working at Brattfors. They are of 2,000 H.P. output each, and generate at 20,000 volts, at which pressure transmission is made, no intervening transformers being required. There are many instances of 10,000-volt directly generating and transmitting plants in use, even with machines down as small as 250 kw. output, but these 20,000-volt generators are the only ones of their kind in Sweden. Another rather interesting generator, designed and built by the author, is one in which no machining has been done to the stator frame. The diameter of the stator of this machine was larger than could be turned in any of the machine tools available, and so the segments of the stator punchings were built up against a ring of 1¼ in. bolts passing through the rough cast-iron frame. These bolts at the same time serve the purpose of clamping the press rings against the packet of laminations after the latter was built up. It often happens on old machines that the laminations shrink, probably on account of shrinkage of the insulation material between the plates. In order to safeguard against the possibility of the entire package of laminations dropping out of the stator frame, should the upper half of the latter be lifted after some years when the laminations had shrunk, ¼ in. steel pins were passed through holes in the laminations and the cast-iron flanges on each side of them and riveted over after the laminations were built up in place. This machine has been running night and day at full load and frequently for long periods (weeks at a time) at considerable overloads since the beginning of 1906, but no loosening of the laminations can be noticed, although it has been subject to frequent short-circuits.

(To be Concluded.)

THE AUTOMATIC REGULATION OF ALTERNATORS.*

BY M. SEIDNER.

(Concluded from page 6.)

Summary.—After discussing the object and possibilities of regulation, and outlining the general theory, the author passes on to discuss regulators of general interest, and more especially those types due to Alexanderson, Walker, Thury and Tirrill, which are of practical value.

Description of Some Methods of Regulation.

This abstract will be concluded with a description of a few of the more important and successful pressure regulators.

Alexanderson.—Among those in the *first* group probably that due to Alexanderson possesses the fewest weaknesses. His system is shown in Fig. 2. The exciting coils N of the three-phase generator G are excited by current produced in the special winding *Sp* in the generator, and by the current transformer *St*. This current is then rectified by the two-segment commutator K. Each of these segments extends over an angle of 120 deg., and there are three brushes placed at 120 deg.; consequently two brushes will stand on the same segment for a short time, and an equalising current—which is damped by the resistances R and *r*—will flow. *Sp* and *St* are in series with *r* between, and are both in parallel with R. At no-load the current *Sp* will flow through R; thus the pressure *Sp* must be considerably smaller than if the no-load current had to pass through the highly inductive transformer *St*. Consequently the no-load current is almost a pure watt current. On load, the current transformer impresses an E.M.F. on the circuit of the pressure transformer *Sp*, which, with increasing phase displacement, comes more and more into phase with the pressure *Sp*. Hence the current in resistance R will fall as the load and phase displacement increase, and in the same ratio the commutated current will increase, which we have seen is the condition for correct compounding. The part played by the resistance *r* is to diminish the phase displacement of the current and to produce as nearly a watt current as possible at all loads.

The commutator interrupts the current in each of the three phases periodically, and the resultant exciting current will pulsate very little; the special pressure winding is only used to do away with the self-induction of the potential transformer. Despite the small magnetic energy (due to the absence of wattless currents), the interruption of the current may still lead to sparking, and to overcome this, Alexanderson sends compensating current through the brushes, which reduces the current to zero in the phase undergoing interruption. This is obtained by shifting the brushes, whilst the equalising current completes its circuit through the resistances.

The various arrangements classed in this group all present sparking difficulties. Their factor of safety is not less than that of ordinary generators with exciters; the speed of regulation is all that could be desired, whilst over-regulation or instability is not possible. A great disadvantage of all these methods is the large commutator required with multi-polar machines, also large transformers are required and considerable energy is consumed in the resistances.

Rice.—As a practical example of the *second* group we can take Rice's method, which the General Electric Co. has developed and applied to a number of high-speed generators. The no-load exciting current is taken from a standard exciter, whose frequency is the same as that of the generator. Thus, if the exciter has the same number of poles as the alternator, it can be direct coupled, otherwise it must be driven through gearing. The alternating-current side of the exciter is connected in series with the alternator through a current transformer, so that the exciter E.M.F. opposes that of the generator. As seen from Fig. 3, the exciter E excites itself and also the generator G. At no load the exciter E provides the current transformer *St* with magnetising current, and the terminal pressure of the

* Abstract of an article in the "Elektrotechnische Zeitschrift."

Digitized by Google

generator falls due to the pressure induced in the primary of the current transformer. On load the exciter is compelled to take the current of the alternator. This is a motor current, so that armature reaction will increase the excitation of the machine E. Hence its terminal pressure will rise as the load rises and as the phase displacement increases, which is what is required.

The method due to Danielson is almost identical with the above in principle, but the great weakness of both is the necessity for having the exciter running at the same frequency as the alternator. The factor of safety of these arrangements is good, and the commutation conditions favourable, but the speed of regulation none too satisfactory, owing to the changes that have to occur before the exciting current can be varied. The pressure changes are not retarded, but also are not made more frequent, which is an advantage compared with the methods in the first group.

The methods included in the *fourth* group are the nearest approach to inherent pressure regulation with respect to safety of working. If it were possible to find a method based on armature reaction that did not require any special construction of the generator, such a method would be the ideal solution to the problem of pressure regulation.

Walker.—The method due to Walker is based on the cross magnetising or watt component of armature reaction. This component displaces the magnetic axis from the centre of the pole by magnetising the one side of the pole and demagnetising the other, whilst the resultant flux remains practically the same. If now the demagnetising component can be neutralised, the magnetising component will be left and will increase the excitation as the current increases. Walker does this by saturating at no load those halves of the poles where the demagnetising effect acts and leaving the other half unexcited, so that when the load comes on, the former part will scarcely be affected, whilst the latter becomes magnetised.

This arrangement has a disadvantage. As is known, the pressure drop depends chiefly on the wattless component, but the present

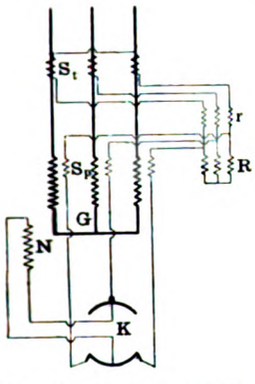

FIG. 2.—ALEXANDERSON'S ARRANGEMENT.

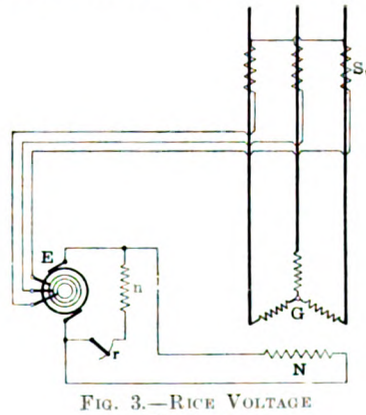

FIG. 3.—RICE VOLTAGE REGULATOR.

method cannot compensate for this, so that this device is only applicable for high power-factor loads (not less than $\cos\phi = 0{\cdot}85$). Despite this disadvantage, the method has been used by the British Westinghouse Co. for turbo-alternators.

In all the static methods of regulation discussed above the primary current is used to compensate the pressure drop it causes. On the other hand, the mechanical regulators now to be described are operated by the primary pressure variations. They act by varying the shunt rheostat of the exciter until the primary pressure is restored.

Static regulators do not retard the pressure changes, but even augment them, and increase the pressure rise due to change in speed. Astatic regulators, however, are very sensitive to pressure changes, and possess the tendency to prevent all variations in the pressure.

N.B.—An astatic regulator is one which is in equilibrium in any position when the pressure is normal. On the other hand, it will continue to operate until the pressure becomes properly adjusted.

Thury.—Thury's regulator is one of the most complicated though one of the best constructed. By a mechanism actuated to and fro by a small motor, the wheel of a shunt resistance is rocked forwards and backwards, and operates a control magnet. Regulation, therefore, takes place step by step, and is consequently very slow. The principle is seen from Fig. 4. The arm D, on which the escapements I and I′ are fixed, is kept swinging by a small motor. I and I′ are kept pressing on the toothed wheel H, the axis of which operates the rheostat. The levers K and K′ prevent I and I′ gearing into the teeth of H, so that the arm D cannot set the toothed wheel in motion so long as K and K′ retain their mid position.

The two levers K and K′ can be brought into their middle position by the double-acting lever E. When, however, K is shifted, the lever K′, in moving to the left, knocks against the contact C and sets the lever free, whereby the escapement I′ engages with the toothed wheel and moves the latter in a clockwise direction until E takes up its central position again.

On the other arm of the lever E the electromagnet B is fixed, which is excited from the terminal of the machine being regulated. The apparatus is adjusted so that with normal pressure the pull of the magnet B and the springs A and R keep the lever E in the central position. The toothed wheel can make one revolution in 30 seconds, so that if the contacts extend over two-thirds of the circumference the whole resistance can be switched in or out in 20 seconds. This speed, therefore, is rather too slow to be satisfactory. To prevent hunting, an oil damper, N, and spring O are added to check the movements of the lever E. The chief application of the Thury regulator is for lighting loads to maintain constant pressure without hand regulation. For regulating the pressure of alternators it is not so suitable.

Tirrill.—With respect to speed and accuracy of regulation, and at the same time an absence of over-regulation, the Tirrill regulator is the best mechanical regulator yet brought out, and is based on an entirely different principle from the foregoing. At one single step the whole of the resistance is inserted or cut out of the field circuit of the exciter, the time taken being 0·1 to 0·05 of a second, so that regulation is very rapid. To prevent the pressure surging or hunting the principle of "back control" is used, which now finds application in all modern indirect-acting mechanical regulators. In all previous descriptions of the Tirrill regulator neither the existence nor importance of the back control have been recognised, so that this important factor has not been fully appreciated. The characteristic property of this regulator does not only consist of the con-

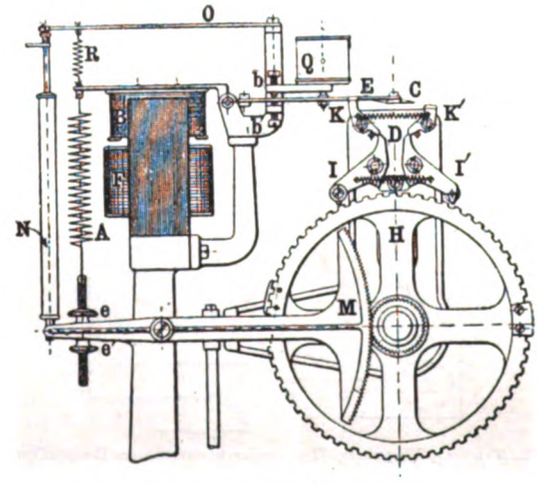

FIG. 4.—THURY REGULATOR.

tinuous switching in and out of the whole shunt resistance, but in its conjunction with the action of the back control.

In Fig. 5, let the coil Sp of a solenoid be excited with the pressure E of the alternator being regulated, and let the solenoid be adjusted so that with a certain pressure it attracts the iron core K_2, it breaks the contact made by C_1 and C_2, and with a lower pressure makes the same. The contact pieces C_1 and C_2 are made either to short-circuit the resistance r or insert the same in the exciter field circuit. If the machine pressure is less than that required to operate the apparatus, the contact is closed and the shunt resistance short-circuited. The pressure of the exciter, and with it that of the generator, will then continue to rise until the pressure is reached which causes the coil to be attracted and the contact broken. The sudden insertion of this resistance causes the pressure again to fall, but only momentarily, for the contact is again closed as soon as this takes place. It is thus clear that the core will swing to and fro like an electric bell, and the shunt resistance is continually inserted and short-circuited.

Owing to this switching in and out, the exciting current will maintain a periodic fluctuation between a maximum and minimum, and the mean value of the current will be larger the longer the period during which the resistance is short-circuited. This fluctuation will also appear in the terminal pressure of the alternator to such an extent as to make the use of the apparatus in this form impossible.

On account of the inertia of the magnetic fluxes and the mechanism over-regulation will ensue. To accelerate the regulation and overcome the inertia of the flux, Tirrill uses a very large shunt resistance in the field circuit of the exciter, so that when this is inserted or cut out the pressure of the exciter and alternator change suddenly, in order to reach a stable condition, which, however, lies well beyond

Digitized by Google

the desired limit. The rough pressure variations must then be fixed in this way and the finer variations adjusted when the desired pressure is reached. The regulator, therefore, must act suddenly and at the exact moment in order to prevent a too large pressure variation occurring. Should this not occur at the right instant, the terminal pressure will at once begin to vary over wide limits, and a considerable over-regulation takes place. This latter is an inherent property of indirect regulators. By indirect regulators is meant devices where the governing mechanism does not produce equilibrium between the energy input and output directly, but indirectly by means of an auxiliary motor controlled by a relay.

The above depicted regulator consists of such a relay, and, with the exciter, has all the properties of an indirect regulator. Assume now the load is suddenly removed from the generator. The consequent pressure rise raises the core K_2 and inserts r in the exciter field. The pressure will not fall immediately, but continue to rise, for a certain time must elapse before the magnetic inertia is overcome. At the moment when the alternator pressure reaches its maximum, equilibrium exists between the continuous and alternating current ampere-turns. Since, however, the pressure is above the normal, the contact C_2 moves still lower, and the pressure falls until it reaches its proper value. The contact C_2 at this instant reaches its lowest position and comes to rest. As soon as the pressure falls below its normal value the core K_2 will begin to sink and C_2 to move upwards, and at a certain value of the pressure the contact is again closed and the operation is repeated again in the reverse sense. But the contact C_2—owing to the inertia of the movable part of the apparatus—will not come to rest at the instant the pressure reaches its proper value. The pull of the magnet Sp must fall off considerably to retard the moving masses and give them an acceleration in the opposite direction. Consequently, the moment of contact will be displaced and the lower limit of the pressure reduced. This limit will not be the same as when the contact is again closed. When the contact is made the exciting current and pressure do not immediately

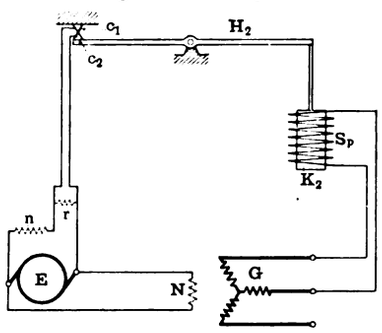

FIG. 5.—TIRRILL VOLTAGE REGULATOR WITHOUT BACK CONTROL.

rise, but after some little time, during which the pressure sinks further—even below the limit which sufficed to make the contact.

To prevent this over-regulation in indirect-acting regulators advantage is taken of the principle of "back control," as seen above. Over-regulation is due to the retarded completion of regulation. The movement of the mechanism which directly effects the regulation lags behind the movement of the governing mechanism, so that the regulator is not able to complete the regulation within the time over-regulation could be avoided. The principle of back control consists of taking away the task of completing the regulation from the governing organ and conveying it to the working part of the regulator directly responsible for effecting the regulation. The working part in this way comes to play an independent part; it finishes the regulation and brings the whole regulating device back into its position of rest, in which then the governing mechanism can exert a new impulse for a following regulation. By means of this back control the regulation can be completed at any pressure within the period of regulation. It is possible, for example, to complete the regulation at the moment when the pressure reaches its normal value, or even earlier. The time taken to complete the regulation depends only on the movements of the governing mechanism and the working part.

The working part can be brought into action during regulation in a variety of ways, as illustrated by the different kinds of hydraulic regulators. Usually the governor is operated by a lever, one end of which moves the regulator and the other the auxiliary motor. With alternators the exciter acts as the auxiliary motor. Tirrill moves the contact C_1 by means of the exciter pressure, so that both C_1 and C_2 are movable.

Tirrill's regulator differs from the above-mentioned indirect-acting hydraulic regulators in one particular. In the latter the working part completes the regulation process entirely, and the governor valve brings the apparatus back into its position of rest. In the Tirrill regulator, on the other hand, the working part not only completes the regulation in the direction in which the regulator started to act, by bringing the governing mechanism back into its position of rest, but the governor valve is also set in the opposite direction, so a regulation in this sense is set in action. Thus the Tirrill regulator has no position of rest. The working part is continually changing over, and not only completes the regulation, but also starts the same. An exactly similar action would take place in a steam turbine if the working part were allowed to carry the governor valve beyond the equilibrium position and bring itself to a movement in the other direction.

The arrangement of the Tirrill regulator can be seen from Fig. 6. The double-acting lever H_2, together with the parts belonging to it, are identical with those in Fig. 5. The contact C_1, however, is no longer fixed, but is attached to one end of the double-acting lever H_1, whose other end is operated by the spring F and relay Sg. Sg is excited from the terminal pressure of the exciter. Thus the contact C_1 C_2 is not only affected by the alternating current, but also by the continuous current of the exciter. The magnet Sp, as before, is astatic—that is, it comes to rest in any position with the proper pressure. On the contrary, a small variation in the pressure raises or lowers the core K_2. The other magnet Sg is static; each position corresponds to a definite pressure. The movement of K_2 is damped by a dash-pot, B.

Suppose the pressure of the alternating-current generator to fall, then Sp cannot counterbalance the astatically balanced core K_2, so that the latter falls and the contact C_1 C_2 is closed. As a result of this the pressure of the exciter and generator rises. If C_1 were fixed, the generator pressure would continue to rise until the movement of K_2 reversed and the contact interrupted. Actually, however, the magnet Sg draws the statically balanced core K_1 down as soon as the pressure of the exciter rises, so that C_1 rises and interrupts the contact and tends to come to rest. If the pressure of the generator is still too low, C_2 rises still further, and prevents the contact

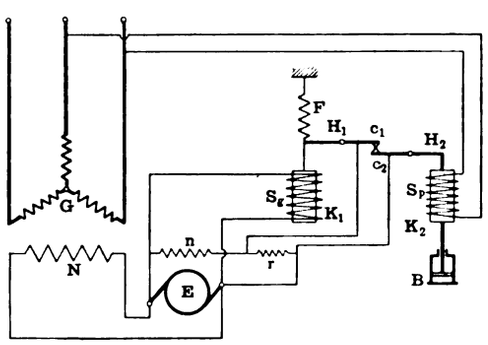

FIG. 6.—TIRRILL VOLTAGE REGULATOR WITH BACK CONTROL.

being broken. As soon, however, as the pressure approaches its normal value, the movement of C_2 is retarded and cannot follow C_1, so that the contact is broken and the action begins again in the opposite direction.

The regulation, therefore, is not concluded by the backward movement of C_2 caused by the over-regulation, but, before this can occur, by the upward movement of C_1. Thus the over-regulation has been reduced, the time of regulation decreased and the non-uniformity diminished.

The levers H_1 and H_2 are thus in constant swinging movement, even when the pressure has not altered. When a pressure change does occur, both levers change their position. The lever H_1 always assumes the position where the exciter pressure keeps the core K_1 in equilibrium, and the lever H_2 naturally moves with H_1. The whole movement of H_1 between no load and full load is about 1·5 mm.; the path of the swing about $\frac{1}{20}$ mm. The number of swings per minute varies from 400 to 1,000. The contacts C_1 C_2 are not used to switch in and out the shunt resistance directly, but are made to bring an electromagnet into action, which moves through a long distance and is more effective. A condenser is used to damp the sparking in the circuit.

The important advantage of this regulator is the speed with which the voltage of the exciter is altered, which can only be accomplished by switching in and out the entire resistance. Thus it does not regulate so quickly with large load changes as with small. Further, the regulation is so exact that in this respect it excels all others. But they cannot work in parallel, so that large stations must be governed by a single regulator and the same type and size of machines must be used.

To make these mechanical regulators sensitive to pressure changes due to variations in speed a large ohmic resistance is inserted in the field circuit of the alternator, so that the current in the solenoid becomes independent of the frequency.

ELECTRIFICATION OF STEAM RAILROADS.

The Committee appointed by the New York Railroad Club to investigate the subject of the electrification of steam railroads recently presented its report. The Committee consisted of Messrs. W. J. Harahan (Erie Railroad), chairman, L. C. Fritch (consulting engineer, Illinois Central Railroad), H. M. Warren (Delaware, Lackawanna & Western Railroad), H. H. Vaughan (Canadian Pacific Railway), J. H. Davis (Baltimore & Ohio Railroad), G. W. Wildin (New York, New Haven & Hartford Railroad), W. McClellan (consulting engineer), C. O. Mailloux (consulting engineer), and E. B. Katte (New York Central & Hudson River Railroad). The following abstract of the report is contained in an article in the "Electric Railway Journal."

A number of the most important events in the history of the electric railway are first cited. Then, in referring to the characteristic features of electrification and in connection with the subject of flexibility, it is stated among the advantages of electricity that locomotives or motor cars may be coupled in a variety of ways and operated by means of the multiple-unit system from one point in the train. Public streets and highways may be occupied, if necessary, and operation in tunnels ceases to be objectionable. Trains may be shorter and more frequent, or they may be of any size that business conditions dictate, consistent with mechanical considerations. A distribution of driving wheels throughout the whole train permits high acceleration, which in turn permits increased schedule speed without excessive increase in maximum speed. All of these features have a varying weight according to the circumstances of the particular problem at hand. Referring to weather conditions, the report declares that electric service has been found to be but slightly affected by snow or other weather conditions, and that in cold weather the steam locomotive is at a disadvantage, but not an electric locomotive or motor car. The Committee believed that the electric locomotive would have much less idle time under the same conditions than steam locomotives, and can be designed for practically continuous operation over any length of run. It has also a very much larger power capacity and is much more cleanly.

The principal reasons for considering electrification, in the opinion of the Committee, are an increase of station and track facilities, an increase in gross earnings due to more frequent trains, and legislative enactment. In referring to the increase in gross earnings, however, the report states that the mere substitution of electricity for steam will not accomplish a very great increase in gross earnings, but by changes in schedule and stops the service must be made more convenient and attractive to the desired patrons. Inattention to this feature is preventing some roads at present from realising the full possible returns upon their electrification.

Upon legislative enactment requiring the substitution of electricity for steam the Committee says: The operation of a steam railroad in the heart of a large city is of necessity attended by features not always ideal. On account of the cost of land and other conditions, the amount of space for roadway is likely to be cramped and closely pressed by city and private property. The emission of smoke and gases from the locomotives, especially if a subway or tunnel is involved, often leads the community to demand that the railroad abolish the objectionable features. This demand, in its essentials, may be reasonable enough, and if by calm and considerate discussion it can be shown that conditions are unnecessarily bad, the public has a right to expect the railroads to provide a reasonable remedy. Unfortunately, however, the discussion is sometimes fanned into a condition where hostility and acrimony become the chief features. As a consequence, the public may make demands, the difficulty, expense and result of which it has no conception, and the railroad is compelled to refuse anything like the full extent of the demands because it knows it cannot afford to do otherwise. In this connection the following are a few broad considerations which common-sense and equity present: (1) A railroad has a charter franchise or special privilege from the commonwealth, and, therefore, belongs to a class of activities which must especially consider the interest of the public. (2) A railroad is also a business venture organised to make money, and those responsible to the stockholders must conduct its affairs so as to serve their best ultimate interest. (3) A nuisance, for example, smoke, incident to the operation of a property, whether factory, railroad, store or what not, may be deplored, but all sources of such nuisances must be treated alike, and it should also be determined how far a removal of the nuisance might endanger the industry itself and cause its failure. (4) It is only fair to assume that men who have worked in the public eye, at any particular business, for a number of years, are men of integrity and well informed as to their business. Action should be taken, therefore, by the community only when advised by well-informed persons and after comprehensive considerations. (5) There are not two sides to this problem. The interests of the railroads and those of the public are one.

The Committee made an effort to secure operating data for publication from the existing electrified steam railroads, but this attempt met with little favourable response, because, almost without exception, the men who are responsible for the operation of these properties did not think the conditions were sufficiently settled to permit them to publish data that would be just either to steam or electric operation.

The report concludes as follows: To sum up, the following may be stated as the advantages and disadvantages of electrification:

Advantages.—(1) Increasing the capacity of a given terminal by the elimination of switching movements, where multiple units are used, and increasing the scheduled speed of trains without increasing maximum speed by the higher acceleration possible with electric power; also increasing the capacity of the line and permitting shorter block signal spacing.

(2) Avoidance of smoke and steam nuisance, making unobjectionable tunnels, subways and underground stations, and reclaiming the aerial space above track for offices, stores, warehouses, hotels or other buildings; also a saving in deterioration of metallic structures, because of the corrosive products of combustion in steam locomotives.

(3) Uniform power over grades and greater tractive power of electric locomotives of equal weight with steam locomotives, including tender, making heavier trains possible over mountain divisions. Locomotives may be used in multiple without increasing the cost for enginemen.

(4) Economy of operation under conditions favourable to electric traction, such as frequent multiple-unit train service or cheap electric power as compared with the higher cost of locomotive coal.

(5) Electrical operation has proved itself reliable.

(6) Electric power is not a source of danger to the travelling or general public.

Disadvantages.—(1) A large investment for re-equipping the railroads with the new power, which can only be justified by definite financial or economic results.

(2) Increased danger to employés or the railroad due to the presence of the third rail or the overhead conductor, especially in yards or terminals.

Future Electrification.—The following features with reference to present conditions should be considered, having in view future electrification: (1) The signal system should be designed with a view of meeting the restrictions involved in electrification work. (2) Bridges, yards and terminal platforms should be designed to conform to the clearances necessary for the installation of working conductors. (3) Locomotives and cars should be designed to conform to electrification clearances. (4) The lighting system of cars should be designed for economical use on electrified roads. This applies also to the heating systems. (5) Steam, water, air and gas pipes in yards and at stations should be laid out to avoid current collectors on future electric equipment and working conductors, also bonded to avoid electrolysis.

Conclusions.—(1) No general information is available on the basis of which steam railroads, as a whole, would be justified in electrifying terminals or main lines, solely on the grounds of economy. (2) Careful investigation is necessary to decide if electrification of terminals and suburban districts would be warranted in order to increase earnings. (3) More attention should be given to the possibilities of electrification in connection with heavy grades, and at other places where an increase in facilities is needed. (4) It is not likely that conclusive data on the economy of electrification will be available until electrification is extended over a complete steam locomotive stage. (5) The electrification for passenger terminal and suburban service is now more or less settled as to method, but for freight and general trunk line service it is in the experimental stage. The types of locomotives for various service have not been determined, though progress is being made. The method of secondary distribution (working conductors) needs much development. The third rail is thoroughly reliable and efficient, but unsuitable for complicated switch work. In its present form it has only been used for voltages up to 1,200. The overhead system for high voltage working conductors also needs much development. Few, if any, are satisfied with present designs and many changes are proposed. (6) The steam railroad men and electrical engineers should work together in as close harmony as is possible, so as to produce results that will be as free from mistakes and experiments as is possible in any developing art. (7) Each problem must be studied on its merits, and a decision can only be made after careful study of the conditions pertaining to each situation. (8) The electrification of large freight terminals has not as yet been attempted, nor satisfactorily worked out, therefore it is necessary to proceed with caution in this matter, and the problem

Digitized by Google

must be exhaustively studied and new developments made before it would be justifiable to make such an installation. The electrification of any large freight terminal would involve a number of roads, and cannot be undertaken independently, without the co-operation of all the railroads affected, on account of the relations existing among the various roads in the interchange of freight traffic.

RAPID ELECTROCHEMICAL ANALYSIS: A COMPARISON OF SEVERAL METHODS.*

BY L. S. PALMER AND R. C. PALMER.

Considerable information has appeared in recent years on the rapid deposition of copper, zinc and other metals. Various devices have been employed, such as rotating the cathode, rotating the anode, and lately even rotating the electrolyte. Some experiments on the determination of copper with the apparatus of Frary,† in which the electrolyte is rotated and the electrodes are stationary, led us to believe that the speed with which complete deposition was obtained was not wholly accounted for by the fact that the electrolyte rotated, but depended to a large extent upon the nature of the electrodes. The anode used in the Frary apparatus is a platinum spiral of about 1 mm. diameter; the cathode a platinum gauze, weight about 14 grammes, 15 mesh to 1 cm., size 11 cm. by 5 cm. To test this supposition we conducted a series of tests to determine the relative merits of the two factors—gauze cathode and rotating electrolyte,—in rapid depositions.

Three sets of tests were made with cupric sulphate solutions—one with a rotating electrolyte using the gauze cathode; a second set without rotation of electrolyte using a gauze cathode; and for comparison a series using the usual form of platinum cone as cathode, without rotation of the electrolyte. Two sets of test were made on zinc depositions similar to the first two for copper, with the exception that the electrolyte was cooled by means of water flowing through a lead spiral surrounding the vessel containing it, as described by Frary.‡ The conditions for the copper determinations were taken from data given by Fischer.§ The conditions for the zinc depositions were taken from data given by Frary.¶ At the end of each experiment the solution was siphoned off with the current still on and water added to dilute the electrolyte to prevent the re-dissolution of the deposit. The first 250 c.c. portion was saved for testing the completeness of the deposition by means of the usual potassium ferrocyanide test. In the zinc determination, in place of a nickel gauze cathode as described by Frary,¶ the cathode was plated with copper before each determination.

As a result of these experiments it was found that, under the conditions of our experiments, 0·31 gramme of copper was completely deposited on the gauze cathode in 25 minutes with magnetic rotation of the electrolyte; in 50 minutes without rotation, and in five hours using the platinum cone cathode. That is, the copper was deposited twice as fast with rotation as without, and 12 times as fast with rotation as by the old cone method. It seems from this that the rapidity of Frary's method is due, in a large measure, to the gauze cathode. Another test was made which showed the marked influence of the gauze cathode on rapid deposition, in which, without rotation of electrolyte, 0·5 gramme of copper was completely deposited on a platinum gauze from 50 c.c. of solution in five minutes. A current of 8 to 10 amperes was used with only a few drops of conc. nitric acid. The deposit, however, was slightly spongy.

The data show no difference in the time required for complete deposition of zinc. The only difference shown is that the bulk of the zinc was deposited slightly faster with rotation. Since Frary's result (the deposition of 0·1 gramme in 30 minutes) was reproduced in both cases, we concluded that the lead coil reduced the rotation of the electrolyte to such a large extent that the slight rotation that might still exist had very little effect on the rate of deposition. In fact, there was such a large evolution of gas during the electrolysis that it was difficult to tell whether the electrolyte rotated or not, showing that there was sufficient agitation of the electrolyte from this cause alone to produce the rapid deposition.

The use of the gauze cathode in rapid electrolytic determinations is shown by these tests of the efficiency of Frary's rotating electrolyte apparatus to play a sufficiently important part to warrant its use alone for simple rapid determinations, and thus dispensing with the various mechanical devices for agitation of the electrolyte.

DISCUSSION.

Mr. F. C. FRARY said it would be a very good thing if this Paper and the one by Stoddard (*loc. cit.*) served to call the attention of American chemists to the great advantages which the gauze cathode has over all others. These were first emphasised by Paweck,* and later by Winkler† and others, who made the same point as Messrs. Palmer and Stoddard, that more rapid deposition at a higher current density was possible with its use. Its good points were clearly pointed out by Foerster‡ and Classen,§ and mentioned by Smith,¶ but did not seem to be generally appreciated. It seemed to the speaker, however, that the conclusion drawn from this Paper and that of Stoddard, that the rotation of the electrolyte might be dispensed with entirely was premature, and rested on too slight an experimental foundation. Copper was probably the easiest known metal to deposit with approximate completeness in an adherent form. That such results might be obtained even without the gauze cathode is shown by a Paper read by Prof. Exner before the Minnesota Section of the American Chemical Society in 1907. He showed that copper could be satisfactorily precipitated on a platinum cylinder with stationary electrodes in a short time by simply heating the solution from beneath with a flame, so that convection currents stirred in a little. Great results were hoped for from this method, but did not appear to have materialised. It seemed very probable that 0·3 gramme of copper could be as satisfactorily deposited from the electrolyte used by the Messrs. Palmer upon a platinum dish, without rotation, by 5 amperes in 50 minutes, as upon the gauze electrode. The ordinary cone or cylinder could not be expected to yield such results, on account of the large portion of the solution which was out of the direct line of current flow. But the electrolyte used was hardly the most suitable for the rapid complete precipitation of copper. Withrow|| had shown the retarding effect of large amounts of nitric acid; it might also be seen by a comparison of results obtained here with those given in this Paper. Students regularly get complete precipitation of 0·2 to 0·6 gramme of copper in 12 to 16 minutes with the use of a current of 5 amperes and magnetic rotation of the solution, as against 25 and 50 minutes found necessary by the Messrs. Palmer with and without magnetic rotation respectively. An electrolyte containing, apart from copper sulphate, from 10 drops to several cubic centimetres of concentrated sulphuric acid, and about 2 grammes of ammonium sulphate was employed, and the deposits were a little darker than those from a nitric acid solution, as stated by Winkler (*loc. cit.*), but are adherent and apparently of proper weight. It was also doubtful whether the Messrs. Palmer obtained complete precipitation of copper in any experiments reported here if, as appears from the Paper, this was determined by the use of a ferrocyanide solution. Experience indicated that quantities of copper in excess of a milligramme were often not indicated by this re-agent. Hydrogen sulphide seemed to be the best precipitant. The precipitation of zinc, as described here, was more to the point, but the conclusion that the lead coil largely reduced the rotation of the electrolyte was probably erroneous, since lead, water and air had practically the same permeability.** The authors were undoubtedly deceived by a phenomenon which the speaker had frequently observed with this apparatus, that the surface of the liquid became partly covered with foam or froth, which attached itself to the electrodes and did not rotate much for two reasons: (1) High electrical resistance, due to its porous structure, so that it carried practically no current, and hence was subject to no torque; (2) sufficient adhesion to the electrodes, due to surface tension, to prevent it from being carried around by the moving solution. This phenomenon was especially common in alkaline solutions. The Paper of Stoddard (*loc. cit.*) was inconclusive in its present form, and could not be cited in support of the conclusion mentioned, since he neglected to show in any case: (1) That precipitation was complete. He stated that such was the case, but did not determine the accuracy of his methods of testing. (2) That the precipitate was of proper physical character. In the case of zinc his description showed that it was not. (3) That it represented the actual amount of metal in the solution—*i.e.*, was neither oxidised on account of sponginess, as was often the case with metals deposited at too high a current density, nor deficient in weight due to mechanical losses caused by the same condition. The whole matter was worthy of a thorough investigation, preferably by several parties working independently.

Messrs. L. S. PALMER and R. C. PALMER, in reply, said, in regard to the copper depositions, they had called attention to the fact that their solutions contained considerable quantities of nitric acid. Mr. Frary stated that such solutions were not the most suitable for rapid and complete deposition. As the authors' object was not primarily to see how rapidly the deposits could be made complete, the fact that Mr. Frary and his students were able to obtain more rapid depositions with other solutions had only a remote bearing on the problem. In the case of zinc depositions, the

permeability of lead, air and electrolyte, which Mr. Frary pointed out to be the same, has no bearing on the rotation. The rotation of the electrolyte was due to the number of lines of force or the magnetic flux through it. The lead coil introduced between the solenoid and the beaker evidently took up a large number of these lines of force, causing a smaller number to pass through the beaker itself and thus decreasing the rotation of the electrolyte. However, the question of rotation had no bearing here, as the data showed that the same results were obtained with and without passing current through the solenoid.

ON THE EFFECT OF SHUNTING INDUCTIVE COILS.

BY G. W. O. HOWE, M.SC.

Summary.—The author shows geometrically that although the effective resistance under certain conditions may be increased by shunting a highly inductive coil by a non-inductive resistance, the impedance is not increased.

Under certain conditions the effective resistance of a highly inductive coil is increased by shunting it with a non-inductive resistance. This, at first sight, striking fact has been pointed

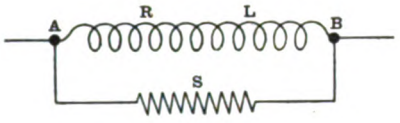

Fig. 1.

out recently by Mr. Albert Campbell (The Electrician, December 10, 1909). Mr. Campbell has worked out the increase of effective resistance, and has given the results of some experiments confirming the formulæ so obtained. He then states that the increase of *impedance* in such cases was pointed out some years ago by Mr. H. E. Harrison. Now, it can easily be shown that the *impedance* is not increased, but that the decrease of inductance is always more than enough to counteract the increase of resistance.

Although this is not very evident from the mathematical treatment, it can be seen at once from the vector diagram. This method has the additional merit of making the whole phenomenon quite plain and of removing the air of mystery.

Without the non-inductive shunt S, the current and P.D. may be represented by the vectors V and C_1. Since the coil

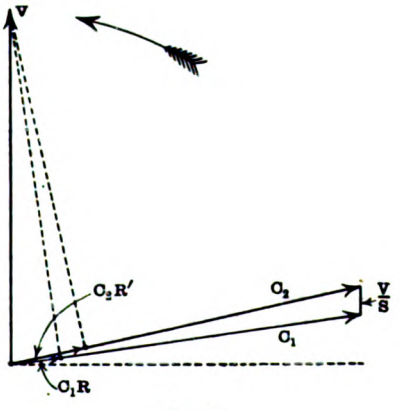

Fig. 2.

is assumed to be very inductive C_1 will lag nearly 90 deg. behind V. When the high-resistance shunt is connected across AB, a small current V/S will flow through it, in phase with V. The resultant current will now be C_2. Since C_2 is evidently larger than C_1, *the impedance has been decreased.*

The effective resistance is obtained in either case by dropping a perpendicular from V on to C_1 or C_2. This gives the energy component of the applied P.D., which must be divided by the current to obtain the effective resistance. The length of the perpendicular gives ωLC. It is evident that C_2 is slightly greater than C_1, that $\omega L'C_2$ is smaller than ωLC_1 and that C_2R' is considerably greater than C_1R, where R′ and L′ are the effective values of the coil when shunted. Hence L′ is smaller than L, and R′ is greater than R.

From the geometry of the figure it is evident that, under the assumed conditions

$$\frac{V/S}{C} = \frac{C(R'-R)}{V} \text{ (approximately),}$$

or

$$R'-R = \frac{V^2}{SC^2} = \frac{Z^2}{S},$$

where $Z = V/C$ = the impedance of the coil only.

This is the formula evolved and experimentally verified by Mr. Campbell.

The correction for distributed capacity in an inductive coil can be obtained in the same way.

We see from Fig. 3 that the perpendiculars alter very little in spite of a large change in the current. Hence

$$\omega LC_1 = \omega L'C_2 \text{ (approximately)}$$
$$\therefore \quad \omega LC_1 = \omega L'(C_1 - C_K)$$
$$\therefore \quad \omega(L'-L)C_1 = \omega L'C_K$$
$$\therefore \quad L'-L = \omega^2 L^2 K \text{ (approximately).}$$

This is the well-known correction for distributed capacity. It is equation (4) in Mr. Campbell's Paper.

While the mathematical method is undoubtedly preferable where an accurate knowledge of the errors and corrections is required, the graphical method has the great advantage of giving one a clear mental picture of the relative magnitudes and phase relations.

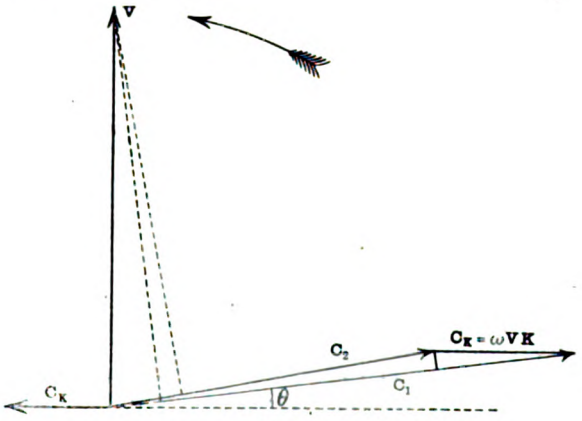

Fig. 3.

It should be stated, in justice to the late Mr. H. E. Harrison, that he does not make the statement with which he has been credited, although the experiment he describes might lead one to imagine that the impedance had been increased by the addition of the shunt.

THE POLARISATION OF DIELECTRICS IN A STEADY FIELD OF FORCE.*

BY W. M. THORNTON, D.SC., D.ENG.

Summary.—This Paper contains an account of experiments on the polarisation of dielectric ellipsoids and cylinders suspended in a steady electric field. From measurements of the field intensity, the dimensions of the ellipsoids and the frequency of torsional swings with and without the field, the dielectric constant is determined. From the rate of increase of the dielectric constant the specific resistance of various substances is calculated.

The slow polarisation of a dielectric ellipsoid suspended in a steady field of force can be followed by observing from time to time the period of small swings about the line of the field.† In a perfect insulator the polarisation reaches its full value in a much shorter time than the period of such a moving system, and a single observation of the latter would suffice to determine the dielectric constant of the ellipsoid. In all solid dielectrics there is, however, slow electrical movement under the influence of the field within the ellipsoid and a consequent accumulation of charge at each end. The restoring couple, and therefore the apparent dielectric constant, increase

* Abstract of a Paper read before the Physical Society. A short account of the discussion was given in The Electrician, February 11, 1910, p. 728.

until the limit to molecular polarisation is reached. The advantage of the method is that the "conduction" current is confined to the separation of charge within the solid symmetrically about the central section.

An account is here given of observations made upon the behaviour of various solid dielectrics, in which the total polarisation is expressed in terms of the apparent dielectric constant. From these observations the resistivity of insulators has been found in a new way. A difference of one part in a thousand in the dielectric constant can be readily measured by the suspended ellipsoid method. On account of this sensitiveness three stages in the polarisation were found to be present in all the homogeneous substances examined. First, a sudden very rapid yield, then a slow change at a uniform rate, and finally an approach to saturation. The first suggests a normal slackness of charge in the dielectric molecule, the second is probably a continuation of the polarisation by the influence of adjacent molecular charges, a slow linear change of the nature of a simple strain. In the third stage the rate of displacement ceases to be uniform, and the polarisation reaches a maximum which is shown in the Paper to be independent of the intensity of the polarising field within the specimen.

According to this "three stage" theory, the quantity passing in the instantaneous charge or discharge of a condenser with a solid dielectric, involving as it does the first stage only, should be proportional to the voltage; the total residual *charge* corresponding to the later stages, the apparent dielectric constant of which is independent of voltage, should also be proportional to the voltage, as shown by Hopkinson* to be the case. Dielectric hysteresis loss should decrease with rise of frequency, on account of the smaller range possible in the second stage, which agrees with the experimental results of Threlfall.† It was found, further, that there was no permanent residual electrification in the dielectrics examined, showing that the polarisation, however long continued, and slow in action, was quasi-elastic in type. When testing electric cables the charging current is sometimes measured after one minute's electrification. With the usual insulators this is only in part a true conduction current, the rest being the second stage of polarisation. What the latter would be in any condenser can be calculated from the curves of rate of change of apparent dielectric constant given later, and in this way the true conductivity found.

Experiments on Quartz.—The quartz was cut parallel to the optic axis and formed into an ellipsoid 2 cm. long and 0·2 cm. diameter. It was very carefully cleaned, dried and suspended by a quartz fibre about 0·001 cm. diameter and 20 cm. long between flat brass plates 6 cm. apart, contained in a vessel dried under vacuum and by phosphoric anhydride for several weeks. The leak between the plates would therefore be exceedingly small, and with a P.D. of 480 volts between the plates the observed periods were the same in dry air and in vacuo. In order to obtain more than two-figure accuracy by this method it is necessary to take the mean of at least five observations of the period. In the first few minutes this was as a rule changing quickly, and it was only in the later stages of the polarisation that several readings could be taken.

Particulars of the form and dimensions of the specimens used in this Paper are given in that dealing with alternating fields.‡ The free period of the quartz ellipsoid was 63·3 seconds. A table in the Paper gives the observed periods in fields of various strength for the first 20 minutes of polarisation. Later observations showed that 20 minutes was not long enough to establish full polarisation. The ellipsoid was therefore re-suspended, having now a free period of 34·73 seconds. After 120 hours in a field of 0·137 electrostatic unit the period was 17 seconds; after 24 hours longer in a field increased to 0·266 unit, 9·72 seconds.

Values of the dielectric constant calculated from the restoring couple on an ellipsoid making small swings in an alternating field of force are in close agreement with the best previous determinations. The assumption made in calculating the couple is that the polarisation is taken up instantaneously in any position, and the agreement shows this to be justified. When, however, the field is unidirectional the components of polarisation are not the same along and at right angles to the axis of the ellipsoid. It will be shown, subsequently, that several days are, in general, required to reach a steady state when the ellipsoid is allowed to stand in line with the field. There is in this position no transverse polarisation, but if the ellipsoid is then given small swings there will be one which alternates with the motion and may thus be considered to be proportional to the constant obtained in alternating fields.

The ellipsoid behaves, in fact, as if it were in effect crystalline, and the restoring couple at unit angular displacement is

$$\left(\frac{\kappa_1}{1+\kappa_1 N}-\frac{\kappa_2}{1+\kappa_2 L}\right)VF^2,$$

where κ_1 is the longitudinal and κ_2 the transverse susceptibility, N and L the longitudinal and transverse reaction coefficients, V the volume of the ellipsoid, and F the intensity of the external field. This couple is equal to $4\pi^2 I(n^2-n_0^2)$, where I is the moment of inertia of the suspended system; n, n_0, the frequency of swing with and without the field.

Hence $$\left(\frac{\kappa_1}{1+\kappa_1 N}-\frac{\kappa_2}{1+\kappa_2 L}\right) VF^2=4\pi^2 I(n^2-n_0^2).$$

Writing $$\frac{4\pi^2 I(n^2-n_0^2)}{VF^2}+\frac{\kappa_2}{1+\kappa_2 L}=a,$$

we have $\kappa_1=a/(1-Na)$, and the dielectric constant

$$K_1=\frac{1+(4\pi-N)a}{1-Na}.$$

For a *quartz ellipsoid cut parallel to the optic axis* L=6·133, N=0·3013, V=0·0534 c.c., I=0·02912, K_0=4·60. From the later set of observations given above n^2=0·0106 in a field 0·266, n_0^2=0·00083. Thus $F^2/(n^2-n_0^2)$=7·25 and a=3·069, giving finally K=508. (Quartz ||.) In the weaker field, F=0·137, $F^2/(n^2-n_0^2)$ =7·16, giving K=610.

An *ellipsoid of quartz cut perpendicular to the axis* had L=6·125, N=0·313, V=0·056, I=0·0307, K_0=4·548. Its free period was 33 seconds. After exposure to a field 0·26 for 48 hours the period was 19·3 seconds: after 41 hours longer in a field 0·132, 26·75 seconds. From these we have the steady values $F^2/(n^2-n_0^2)$=36·5, F=0·26, and $F^2/(n^2-n_0^2)$=36·4, F=0·132, a=0·6705, and K=11·66. (Quartz ⊥).

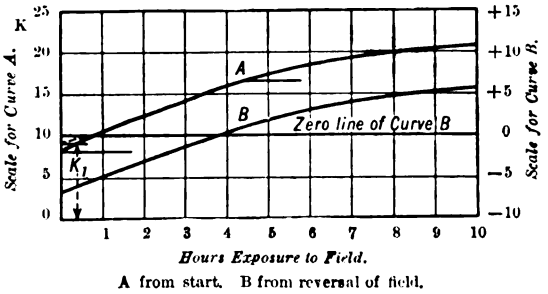

FIG. 1.

Thus both in alternating and direct fields quartz || has the larger values, but whereas in the former the ratio of the dielectric constants is 1·012, in the latter it is about 45.

Observations recorded in the Paper show the exceedingly slow rate of polarisation of quartz ⊥ compared with quartz ||. The mean of $F^2/(n^2-n_0^2)$ is 8·81, and since the derived value of K depends upon this we have the remarkable fact that the polarisation approaches the same value irrespective of the intensity of the polarising field. This suggests that the slow polarisation is a consequence of internal molecular attractions started by the initial polarisation and maintained to a limit by the continuance of the field, but not in any way proportional to it.

Fused quartz has been largely employed in the construction of electroscopes for use in measurements of radioactivity. It is conceivable, though not highly probable, that some of the earlier observed feeble radioactive effects may have been in some measure due to the slow absorption of charge by the quartz support, for the rate of charge or discharge of such an instrument must be influenced by the polarisation of the support.

Experiments on Flint Glass.—Similar measurements to those on quartz were made with flint glass specimens. In the case of an ellipsoid, of density 3·3, free period 14·9 seconds, after 22 hours in F=0·271, period 12·33; after 48 hours longer in F=0·136, period 13·9. For the former $F^2/(n^2-n_0^2)$=26·85, and the latter 27·2. Fig. 1 shows the *forced depolarisation* of a dielectric by a method distinct from discharge through a galvanometer. The chief interest lies in the fact that whether the polarisation is increasing from zero or being reversed the rate of change is for a long time the same. It is also noticeable that the time occupied in the linear polarisation is nearly the same in both cases. The value of K before the field was reversed was 25, of which 9 was the sudden rise at the start. At reversal there was a rapid change equal to twice that from zero—*i.e.*, of 18, leaving a polarisation of K=7 in a direction opposite to that of the field. It will be seen that curve B starts from a value—7.

Digitized by Google

The ellipsoid was then exposed to the field for three weeks and acquired a value of K = 6,075. The following numbers give the *free depolarisation* from this high value. The periods from which K was calculated were taken by applying a weak field and measuring the period after it had been on for a minute in each case, after which it was cut off. There is no doubt a sudden rise of polarisation at the moment of applying the field, but since the conditions are the same in each case the figures give an approximation to the rate of relaxation.

Time	10 m.	1 h.	2 h.	3 h.	4 h.	5 h.	19·5 h.
K	6,075	426	79·7	28·0	12·73	9·0	8·17

Four typical substances were next examined, and the results show that for different substances and over a wide range of values the effective polarisation of an insulated rod approaches the same final value whatever the intensity of the field may be.

Rate of Polarisation.—In the foregoing observations of the rate of change of K in steady fields there appear then to be three stages, a sudden yield, followed by a change at a uniform rate for intervals of time differing in the various substances from a few minutes to several hours, and later an approach to saturation. In order to see how these, especially the second, hold over a wider range of substances a number of measurements were made. These show that gutta-percha, upon which so much depends in the working of submarine cables, has the highest values of all the substances examined. It is at least possible that some of the difficulties of cable working arise from this cause. If by mixing a suitable insulator of lower

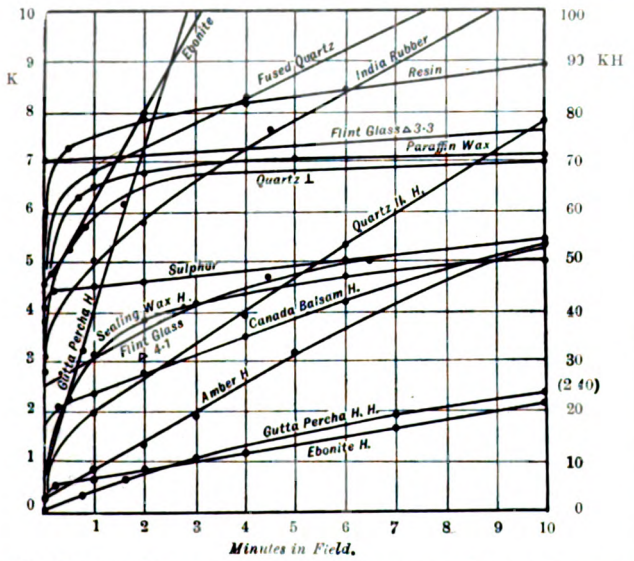

FIG. 2.—RATE OF POLARISATION OF DIELECTRICS IN STEADY FIELDS.

dielectric constant with it, or by some system of grading, retaining at the same time the impermeability to water, the effective constant could be reduced, the rate of signalling might be accelerated. Curves of the rates of change are given in Fig. 2 for the first 10 minutes of electrification, and it will be seen that the features of a rapid rise at the start and a straight line change following it are present in all but sealing-wax, a mechanical mixture. The linear change in most cases lasts for several hours. In the case of fused quartz the polarisation is steady in half an hour, and no increase was observed after several days in the field. This rapid polarisation is possibly the reason for its use as an insulator in electroscopes. The initial rush is in almost every case over within a minute. This may explain why observations of cable resistance are taken after this interval.

Measurement of Specific Resistance.—The fact that the rate of change of the effective dielectric constant is uniform for some time after the field is applied, provides a method of measuring the specific resistance of a dielectric during polarisation as distinct from that using the "time of relaxation." Whatever the nature of the electrical movement during the polarisation of an insulated ellipsoid may be it is in effect a current, the density of which is the rate of change of the total polarisation in unit volume. The field within the ellipsoid is given by $F_1 = F/(1+\kappa N)$, where $\kappa = (K-1)/4\pi$. The polarisation is then KF_1, and writing the apparent specific resistance ρ, we have $\frac{d}{dt}(KF_1) = \frac{F_1}{\rho}$. The resistance measured in this way differs, though not to a marked extent, from that found by the passage of a steady current through the dielectric.

Specific Resistance of Dielectrics at 17°C.

Indiarubber	$1{\cdot}5 \times 10^{15}$		

It may be said that in view of the facts of slow polarisation the measurement of the current after one minute's electrification is meaningless as an indication of the resistance of the insulation. A large part of the current is polarisation change. The leakage method of measuring the resistance of insulators is also complicated by this slow depolarisation of the dielectric and greatly influenced by the time of charge. We have from the above

$$\frac{\rho}{4\pi}\frac{dK}{dt} = 1 + \left(\frac{K-1}{4\pi}N\right),$$

from which ρ may be found at any stage of the polarisation. Since the measurements are in electrostatic units, ρ is also, and in electromagnetic measure is $= v^2\{4\pi + (K-1)N\}/dK/dt \cdot 10^9$ ohms per centimetre cube, where v is the ratio of the electromagnetic to the electrostatic unit of charge.

The above table gives values of the specific resistance found in this way from the observed rates of change of Fig. 2. The indiarubber and gutta-percha were not specially prepared for cable work. The ratio of Curie's values for quartz ⊥ and ∥ is 240; those now

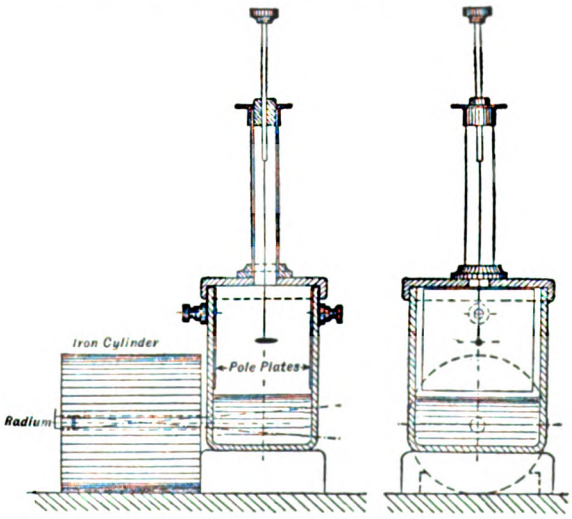

FIG. 3.—TESTING CELL FOR EXPOSURE TO RADIUM.

obtained give 130. It is interesting to note that the velocity of light in quartz is greatest when the wave-front and current are in the direction of least electrical conductivity. In accordance with previous observations the lighter flint glass has the higher resistivity. Paraffin-wax was the most perfect insulator examined.

Slow Polarisation.—The electrical movement within the substance during slow polarisation may be a translation of free electrons, as in metallic conduction, a transfer of charge, as in electrolysis, or a separation of the internal charges of the molecule, so that its electrical moment increases. In order to determine which of these occurs in the present case, a flint-glass ellipsoid was suspended in a glass cell (Fig. 3), the upper part having pole plates, so that a field could be maintained there, and the lower being filled with disulphide of carbon. Outside the cell a massive iron cylinder was placed, having a small central hole pointing towards the line of suspension. The ellipsoid was exposed to the field for several days, and its steady period noted. It was then lowered into the liquid and exposed to the radiation from a strong tube of radium bromide placed in the end of the iron cylinder. After five minutes' exposure the ellipsoid was raised, allowed to stand in the field for the same time that it had been removed from it, and its period then found to be unchanged. The liquid was used to shield the specimen from any ions which might possibly gather on it from the poles, and to prevent any change in the gradient between the poles by the diffusion of ions from the line of the radium discharge. If the charge on the ellipsoid had been in any sense free, whether residing on the surface or inside, it would have been rapidly removed and the period

lengthened by exposure to the radium. The experiment was repeated with the conditions varied in several ways with always the same result. It would appear from this that the electrical movement in a dielectric when isolated in the field is entirely confined to the molecule, and is therefore neither metallic nor electrolytic in type, but is the continued displacement of the atomic charges to a greater degree of separation than has been hitherto recognised.

It may be remarked here that the high values of the dielectric constants obtained in the Paper are confirmed by measurements on electric cables. Ashton* found that an ozokerit-ised rubber cable charged at 20·5·5 volts for 7,200 seconds absorbed $13·8 \times 10^{-5}$ coulomb. From the given dimensions the dielectric constant corresponding to this is 13·1. In this case also the slow polarisation was elastic in type, as shown by the fact that the quantity discharged on short-circuit was just twice that absorbed at constant potential.

It was early suggested by Mossotti that the behaviour of a dielectric can be explained on the assumption that it is made up of isolated conducting spheres. On any of the present electronic theories of matter the separation of charge under the influence of the field gives an arrangement similar to this. It is now suggested that the first stage of polarisation produces such a charged system, but that it differs from a system of conductors in that the charges undergo further separation automatically by reason of the attraction and quasi-elastic approach of opposite charges on adjacent molecules. The limit of the first stage of rapid polarisation is that of the rearrangement of atomic charge within the molecule, that of later stages the establishment of electrical strain throughout the mass under new conditions of internal stress set up by the first polarisation.

The range of the dielectric constant in the first stage may be taken as the intercept on the vertical axis in Fig. 2. Writing this K_0, it is of interest to compare it with the values found for the same substances in alternating fields,† as in the above table. The influence of frequency may from this be anticipated. For those substances in which the ratio is nearly unity it will be at low frequencies small, but for the first few in the list a greater change may be expected between zero and 80 alternations a second than from 80 to the frequency of light.

THE CHANGE-OVER TO CONTINUOUS CURRENT ON THE WASHINGTON, BALTIMORE & ANNAPOLIS RAILWAY.‡

This railway, which previously employed single-phase apparatus for operating its cars, substituted a 1,200-volt direct-current equipment on February 15th last. The reason for making the change is stated to have been the lighter weight of the continuous-current equipment. The Company's 60-ton cars, equipped for operation on the single-phase system, could not enter Washington because, owing to the limited strength of the yokes which support the city tracks, the maximum weight of the cars was restricted to 40 tons. As the railway company desired to run into the centre of Washington, it was confronted with the problem of securing a car of this weight equipped with motors of sufficient size to provide the high speed and high-class service required by the character of its patronage. A careful investigation of the engineering features involved showed that it was impossible to meet these requirements with the existing single-phase equipment. The Company then made an investigation into the relative merits of the two direct-current systems, and found that a large saving in first cost and operating expenses would result from the adoption of the 1,200-volt system in preference to the 600-volt.

The results under the new system substantiated the expectations formed of it. During the first day of operation the cars ran over 4,500 car-miles, and not a trip of the regular schedule was lost. Moreover, a saving of over 25 per cent. in energy was indicated by the watt-hour-meter records of the first few days.

Energy is still purchased from the Potomac Power Co., and is transmitted three-phase to the sub-stations at Ardmore, Naval Academy Junction, Annapolis and Baltimore, at a potential of 33,000 volts and a frequency of 25 cycles. The transformer primaries are Y connected and the neutral point is earthed. The transmission line is in duplicate, the conductors being of aluminium. The sub-station equipment consists of rotary converters, each set comprising two 300 kw. machines operated in series to supply energy at a potential of 1,200 volts. The converters operate in every way similarly to standard 600-volt machines, and are started from half voltage taps on the transformer secondaries in the usual manner. For the protection of the sub-station apparatus 33,000-volt aluminium lightning arresters are installed. Each transmission line is protected by an overhead earth wire.

The rolling stock consists of 30 passenger cars and three service cars. Each passenger car is equipped with four 75 H.P. 600-volt commutating-pole railway motors, and each service car with four 140 H.P. 600-volt motors, also of the commutating-pole type. The motors are insulated for 1,200 volts and are joined permanently two in series for 1,200-volt operation. The cars are equipped with automatic-relay control and have control couplers for operation in trains if desired. A potential of 600 volts for controlling and lighting the cars is obtained by means of a motor-generator, as on other 1,200-volt equipments. This is used only on the 1,200-volt section. On the 600-volt section the control lighting circuits are supplied direct from the trolley. The cars are equipped with Westinghouse automatic air brakes with graduated release. The air compressors are operated by 1,200-volt motors.

The cars run over the tracks of other companies in Baltimore and Washington, and have, therefore, to operate with a 1,200-volt single trolley and earth return; with a 600-volt double overhead trolley metallic circuit; and also on the 600-volt underground conduit system. The earth connection for single-trolley operation is obtained by means of a circuit through the negative trolleys and their holding-down hooks in such a manner that when either negative trolley is raised for operation on the double overhead trolley section the earth circuit is broken. The change from double-trolley overhead to conduit is made by a double-pole double-throw transfer switch, which may be operated either by compressed air controlled from the motorman's cab or by hand. All the electrical apparatus, both for the original single-phase and for the later direct-current equipment, was furnished by the General Electric Co., of Schenectady.

ELECTRIC DRIVING OF A LEAD MILL.

Messrs. Foster, Blackett & Wilson, who have for the past 50 years been established at Hebburn-on-Tyne as well-known lead manufacturers, recently decided to equip electrically the whole of their works. The contract was entrusted to Messrs. C. Martin & Co., of Newcastle-on-Tyne, the wiring to Messrs. Warren Beattie & Co., of Middlesbrough, and the complete equipment of motors, auto-starters and controllers to the British Westinghouse Electric & Mfg. Co. The result of last year's running has, we understand, fully justified the decision arrived at.

The raw materials are hauled in trucks by a single drum haulage running from the company's private jetty on the Tyne. On conversion, the crankshaft of the vertical double-acting steam engine formerly used was taken out and a gear wheel and countershaft put in, by means of which the haulage is now driven by a 60 H.P. motor operated by a drum controller. In carrying out the conversion, care was taken to avoid delays, by using as far as possible existing gear. The capital outlay, therefore, was kept down, and is, we are informed, very low for this class of work. The process of conversion was carried out without a shut-down and without any serious hitch in the operation.

In the separating house, the lead pigs are refined and the pure lead is run into a mould about 8 ft. square, in which a mass of metal, weighing about 8 tons, is formed. This metal slab, lifted by a jib crane, was formerly operated by a two-cylinder, double acting steam engine. The crankshaft and cylinders of the engine were taken out, a countershaft and gear wheel put in, and the drive effected by a motor and drum controller.

The lead mill has rolls about 20 in. in diameter and 8 ft. 3 in. long. Six live rolls, standing in series, facilitate the passing of the billets through the mill. The flywheel, which weighs 7 tons, and has a diameter of 19 ft., was retained for equalising the load on the motor. In contrast with this, the motor is almost lost sight of.

FIG. 1.—HAULAGE CONVERTED TO ELECTRIC DRIVING.

The mill was originally driven by a two-cylinder horizontal engine of 200 I.H.P. and 4 ft. 5 in. stroke, working at 60 lb. steam pressure. On conversion, the crank was replaced by a gear wheel, and the countershaft carrying the pinion engaging this wheel is now belt driven by a 90 H.P. slip-ring motor. A pair of rolling cutters at each side of the bed trims the edges of the sheets when necessary, and also acts as a guillotine for cutting the sheets into lengths, both of these being operated from the gearing of the mill.

We gather that the electric drive now installed has largely increased the output of the mill, in consequence of the steadier drive afforded. A 3-ton jib crane used for loading the finished lead from the mill bed has been equipped with a 10 H.P. motor, the motor and controller being mounted on a bracket which swings with the crane. Two pipe presses lie adjacent to the lead mill. each consisting of an hydraulic press forcing the solid lead out of a steel container through a die. A steel core bedded in the container settles the inside diameter of the pipes, which can be made from $\frac{3}{16}$ in. to 9 in. inside diameter, a maximum hydraulic pressure of $3\frac{1}{2}$ tons per square inch being exerted on an 18 in. diameter ram. The flywheel of the three-throw plunger pump, formerly steam driven, has been replaced by a 6 ft. diameter pulley belt driven by a 30 H.P. slip-ring motor. In addition to the quiet drive now obtained, there has been considerable improvement in the class of pipes turned out. owing to the even turning moment of the motor.

A group of machinery, consisting of a lathe, flue paddles, circular saw and cupola blast fan, formerly driven by an old type horizontal single-acting steam engine, is now driven by a 20 H.P. motor. Five overhead electrically-driven jib cranes are used for loading and unloading the sacks. This is a great improvement on the nine cranes formerly used, these being driven through an endless rope by a 50 H.P. gas engine. The simplicity, convenience and economy of the electric drive is strikingly demonstrated.

The two white lead grinding equipments driven by two steam engines (one of 120 B.H.P. and the other an old beam engine with a 5 ft. stroke and 20 ft. flywheel running at 26 revs. per min.) have been replaced by 50 H.P. motors driving the existing shaft through a belt and a 10 to 1 reduction gear. The two large Torrance mixing machines for converting the white lead into white paint are driven by a 60 H.P. motor geared to the old shafting. This motor also works a 1-ton hoist, an oil pump and a dust extractor. The grinding plant is driven by a 50 H.P. motor geared to the original shafting. On account of the danger which might occur from heavy overloads, a large-faced ammeter is placed in front of the operator with a danger line indicating the overload point.

A dust extractor fan and a mixing and sifting machine are driven by a 10 H.P. motor, and a Sturtevant fan about 3 ft. in diameter, running at 900 revs. per min., which is used to avoid dust in the packing rooms, is driven by a 5 H.P. motor. Loose sheet iron covers fixed over the motors and suspended by pulleys from the cross beams protect the motors from dust.

Figs. 1 and 2 herewith show the haulage and part of the works of Messrs. Foster, Blackett & Wilson.

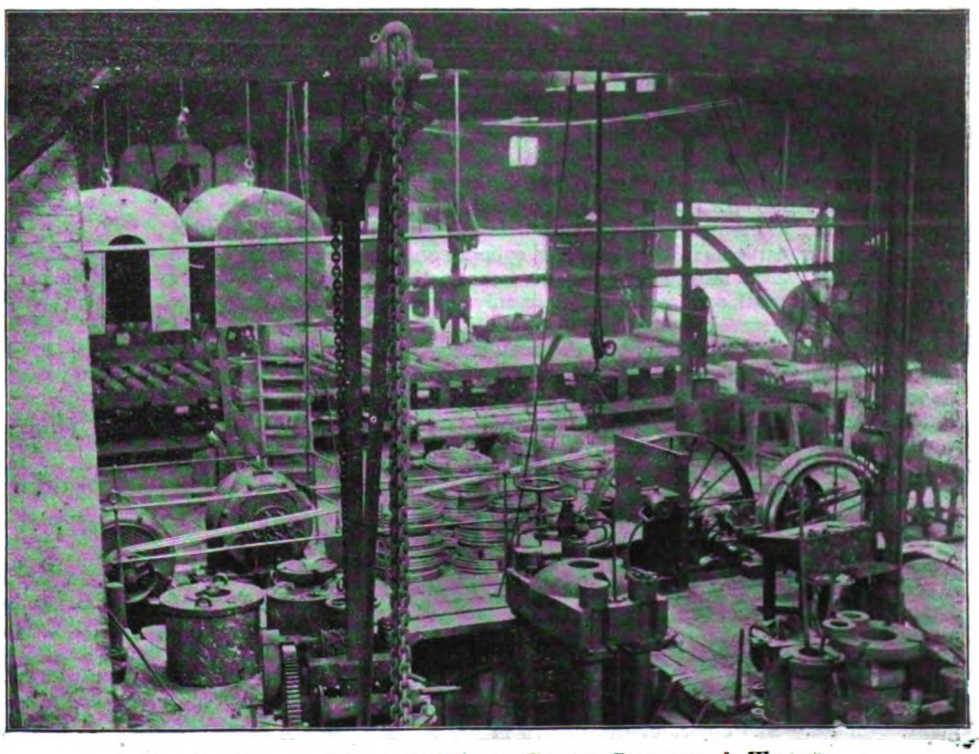

FIG. 2.—VIEW IN WORKS OF MESSRS. FOSTER, BLACKETT & WILSON.

In conclusion, we desire to express our indebtedness to the British Westinghouse Electric & Mfg. Co. for supplying us with the particulars of this interesting installation and with the illustrations.

DEPENDENCE OF THE WEIGHT OF A BODY ON ITS STATE OF ELECTRIFICATION.*

BY L. SOUTHERNS, B.SC.

In a previous Paper† the writer described an experiment designed to detect any alteration which might occur in the weight of a body when its temperature was changed. The present Paper deals with an experiment which seemed naturally to follow the former one—viz., an attempt to detect change of weight due to electrification. A general idea of the method employed may be gained from consideration of Fig. 1. Suppose a delicately but stably-balanced earthed conductor, A, to be placed between two fixed charged conductors, B, C, at potentials $+V_1$, $-V_2$ respectively. Two electrostatic fields, F_1, F_2, will be set up, and these will be quite independent of each other, provided all lines of force from B to C are intercepted by the conductor A, which is at zero potential, or by some other earthed conductor. Charges will be induced on the ends of A, which will now be subject to electrostatic forces which will in general deflect it to a new position inclined at an angle, say, θ from its original equilibrium position. If now the fields F_1, F_2 be reversed each independently of the other, so that we have B at potential $-V_1$ and C at potential $+V_2$, there will be no change in this deflection θ caused by electrostatic forces, for these are independent of the direction of the fields. But now let us suppose that a gravitation effect exists such as to cause the end of A, which is positively charged, to be a little heavier than the negatively charged end. This will give a deflection $+\delta$, which must be added to θ. The difference between the two observed deflections will thus be 2δ.

There is no theoretical necessity for making the fields or the conductors symmetrical or the potentials V_1, V_2 numerically equal to each other. In practice, however, it is desirable to make the apparatus and fields as symmetrical as possible. With symmetrical apparatus the deflection θ, due to electrostatic forces, will be small, and any deflection due to a gravitation effect will be more readily observed. The form of apparatus indicated in Fig. 2 is therefore

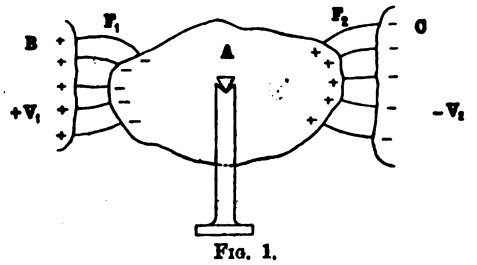

Fig. 1.

adopted. The beam AA with its curved end pieces is supported by a steel knife edge and grooved plate by means of which it is electrically connected to earth. The pierced guard cylinder D and metallic case E are also earthed. The field plates B, C are insulated and connected through a double reversing key to the sources of potential, which are separate for the two plates. Some of the lines of force from these plates fall on the guard cylinder and on the case. The apparatus can be adjusted so that the forces acting on AA are very nearly horizontal, so that they produce only a very small deflection from the uncharged position. This deflection is usually made small for practical convenience, but the resulting value of δ is the same for large as for small deflections. Variations of weight corresponding to $\frac{1}{5000}$ or $\frac{1}{15000}$ mgm. are easily detected in practice. This method of arranging the apparatus and of applying and reversing the fields eliminates several errors which might be expected to cause difficulty in an experiment of this nature. In most of the experiments the balance was screened from any possible external electrostatic effects; this, however, made no difference to the result.

The balance itself is shown in Fig. 3. It is rigidly made, so that the applied electric forces shall not produce distortion. The case, guard cylinder, field plates and beam are constructed of magnalium. Referring to the figure, AA represents the beam with its arresting arrangements *aaa*, B one of the end pieces, CC the guard cylinder and DE the insulated field plates. The beam is electrically connected to the guard cylinder by means of its steel knife edge, which bears on a grooved steel plate attached to a pillar screwed to the guard cylinder. The object of the groove in the bearing plate is to prevent side slipping of the knife edge under the action of the electric forces. The guard cylinder itself is rigidly fixed to the back of the case, and the whole earthed. A small amount of play is allowed between the piece B and the guard cylinder. This allows a few lines of force from D to pass between the two, and some of these will terminate on the edges of B. Those falling on the upper and lower edges in the figure give rise to forces tending to deflect the beam. If everything is symmetrical these forces will be equal above and below, and therefore the beam will not actually be moved. But if B is slightly higher than its central position, the lower gap will be wider than the upper one and more lines of force will, therefore, fall on the lower edge of B than on the upper edge. These will tend to bring B back again to its central position. The beam is always in stable equilibrium under the action of the field. The application of the field, however, affects to a slight degree the sensitiveness of the apparatus as a balance, and it is therefore necessary to have some means of determining the sensitiveness while the field is on. This is provided by the arrangement shown in the upper part of the figure. It is an adaptation of a method employed in a balance de-

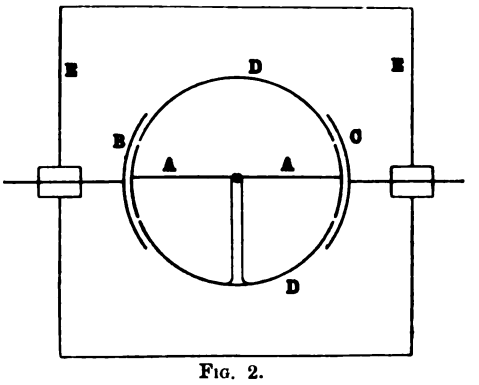

Fig. 2.

signed by Dr. Hicks and used by the writer in the research previously alluded to. A small and feeble magnet is attached to the beam, as shown by the dotted lines at F. This can be attracted or repelled by a small current passing round the coil G. The deflection produced by a given current can be compared once for all with that produced by moving a rider a certain distance along the bar H. By observing the deflection produced by this current during an actual experiment with the plates charged, the sensitiveness can be determined, and the value of any deflection produced by the charges expressed in megohms of weight. The current is not, of course, allowed to pass during actual observations. The deflections are observed by telescope and scale, and a double suspension mirror, the position of which is indicated by the circle K. The field plates D, E are insulated by sulphur plugs, and have various adjustments not shown

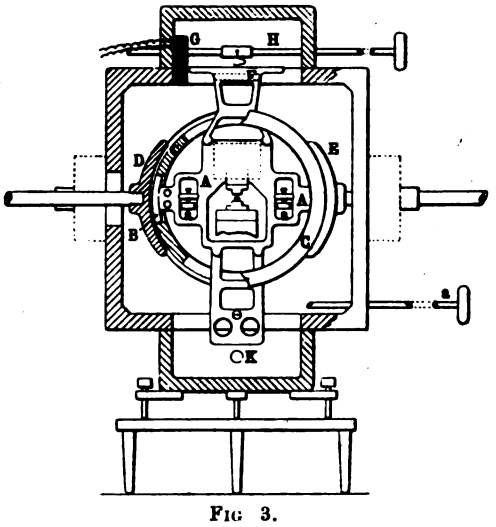

Fig 3.

on the figure. Other details, such as knife edge adjustments, &c., are also left out of the figure to avoid complication. The front and back of the case are of thick magnalium with plate glass windows. The latter have been covered inside with tinfoil in the later experiments, with the exception of a small space for observing the mirror K, which has been closed in with a grid of fine wire. The results, however, are exactly the same whether the windows are covered or left bare. The whole apparatus is enclosed in a box of wood 2 in. thick and provided with double windows of plate glass. The diagram is approximately to scale. The diameter of guard cylinder is 14·3 cm., distance between this and field plates 3 mm., the end pieces B, which are square with rounded corners, 4·9 cm. square. Weight of end pieces about 28 grammes each, total weight of beam about 260 grammes.

*Abstract of a Paper read before the Cambridge Philosophical Society.

Details of the tests and readings obtained are given in the Paper, and also a few sources of error are discussed. The author reaches the following conclusions:—

Conclusions.—Whether the effect be due to a modification of gravity or not, the experiments appear to show that a body positively charged with 20 electrostatic units of electricity behaves as though it were heavier than the same body negatively charged, by an amount of the order of 0·0007 milligrams. If the effect be due to a change in gravity, there will exist in an electrostatic field a small amount of energy due to this cause, and this will involve a very slight alteration in the configuration of the lines of force from that given by ordinary electrostatic laws. This would be so small as to pass unnoticed in ordinary cases. It would be such that, with given conductors charged in a given way and then reversed as to sign of charge, we should obtain two slightly different configurations of field. Delicate instruments might detect this, and it is possible that the different zeros of a quadrant electrometer, with the needle positively and negatively charged, and quadrants earthed, may be due to this cause, though the writer has not investigated these effects, for the explanation of which the above suggestion may be quite inadequate.

It was suggested to the writer that the effects might possibly be caused by an accumulation of air condensed on the surfaces of the metal, the quantity being greater when the surface was positively than when negatively charged. From an experiment made it would appear difficult to explain the result in any such way as this. For we may liken the metal surface to a series of buckets which are filled with condensed air when the surface is charged positively, but empty when it is charged negatively. Now, if we have a number of such surfaces fixed to spokes radiating from a central axis so as to form a kind of wheel (like a water wheel), and place this between charged field plates, we should have all the buckets on one side full and those on the other side empty, and the wheel would revolve. It is difficult to see where the energy would be drawn from to keep up this rotation.

It may be of interest, as a mere speculation, to see whether the theory of gravitation which supposes that the attraction between unlike charges is somewhat greater than the repulsion between like charges, could be modified to suit the present results. Let us suppose that the repulsion between two positive units at a given distance apart is P, and that between two negative units, N, and that the attraction between a positive unit and a negative unit is M. Then the attraction between a neutral body (containing a unit of positive and a unit of negative electricity) and a positive unit will be M−P, and that between the neutral body and a negative unit M−N. The difference between these will be N−P, which is the effect found in the experiments. Again, the attraction between two neutral bodies (each containing one positive and one negative unit) will be 2M −(P+N), and this will be ordinary gravity. The last expression is much smaller than N−P, and thus we should have the result that, while N and P both differ considerably from M, their mean is very nearly equal to M. Since in the attraction M one charge of each kind is employed, it is perhaps not unnatural to suppose that this might be the case. The actual differences between M, N and P would, of course, be exceedingly small in comparison with their absolute magnitudes. Assuming M to be the ordinary electrostatic attraction, we have two equations for finding N and P. It should be remembered that in the experiment, as in this theory, no lines of force pass between the attracting masses. In the experiment the lines do not pass to the earth, but sideways to the field plates. Turning aside from such hasty speculations, the writer would be most grateful for suggestions as to possible sources of error in the experiments, as he hopes to have an opportunity of repeating them later with improved apparatus, the design of which might be modified in view of any suggestions thus made.

PHYSICAL SOCIETY.

At the meeting held on April 8th, Prof. H. L. Callendar, F.R.S., president, in the chair, a Paper entitled

"Demonstration of Telephone Currents in Loaded and Unloaded Lines"

was read by Mr. B. S. Cohen. The demonstration showed the relationship between the sent and received currents in telephone lines under the various conditions which occur in practice. As mentioned by Prof. Perry in his Paper* read before the Society a few weeks ago, it is of little or no practical value to make calculations on the current attenuation in lines of infinite length and with the terminal conditions neglected. The effects of the line length and of the terminal apparatus must be taken into account. By the aid of Prof. Kennelly's formulæ it is possible to calculate the relationship between the sent and received currents under any conditions met with in practice, and for some of the conditions used in the demonstration the calculated results had been obtained. Four essentials were necessary for the experiments shown: (1) A current comparable with the actual telephonic speech current. This was obtained from a vibrating wire interrupter giving a wave with a fundamental of about 100 ∿ per second with a damped oscillation of about 800 ∿ per second superimposed. (2) A telephone line with or without its load in the shape of inductance coils. (3) Terminal apparatus. The lines were terminated by receivers and induction coils as used in practice for what is known as local battery working. (4) Current measurers. For this purpose barretters arranged as alternating-current ammeters were used. The first experiment showed the relationship between the received and sent current for various lengths of standard cable unloaded. The second experiment illustrated the variation in the current sent when the receiving end was open or closed circuited and the length of cable was varied. The third experiment showed the current distribution along the loaded cable by inserting a barretter at different points along the cable. The author gave explanations of the various phenomena illustrated in the experiments. He pointed out that it is now possible to make both calculations and quantitative telephonic tests which give mutual confirmation.

Dr. A. Russell congratulated Mr. Cohen on the admirable demonstration he had given of the effects of "loading" a telephone cable with Pupin coils. He pointed out that much of the success of the demonstration was due to the barretters and the vibrating wire generator which Mr. Cohen had himself perfected. It was now well known that the effect of the loading coils was to improve both the volume of the sound and the clearness of the articulation. He asked whether the diminution in the value of the attenuation constant and the consequent increase in the volume of the sound, or whether the equalising of the velocities of the damped trains of waves proceeding along the wires was of the greater importance in practice. He asked also whether the Pupin coils were inserted in such a way that the going and return currents tended to magnetise the cores of the coils in the same direction. He suggested that the higher efficiency of the loaded cable might be partly due to the diminution in the value of the current and the consequent increase in the value of the potential at the sending end, the gain in efficiency owing to this cause being due simply to the smaller expenditure of energy in heating the wires.

Mr. A. Campbell asked what was the minimum current which would give reasonably clear speech, and what was the usual ratio between the current received and the current sent in good working conditions. The author had used frequencies of 800 ∿ per second. If a line were loaded so as to transmit well at this frequency, would it transmit equally well at frequency 2,000?

Mr. Whalley remarked that the experiments shown did not quite conform with working conditions where constant currents were flowing. He asked whether the results would agree with those which would be obtained with constant currents flowing in the circuit.

Dr. W. H. Eccles called attention to an apparent paradox which arose when the barretter at the receiving end was giving a larger reading than the similar instrument at the sending end of a cable. The barretter deflections were, of course, a measure of the *power* being sent in the instrument, and the paradox might be expressed by saying that in the above circumstances the power indicated at the receiving end was greater than that indicated at the sending end. The series of detached trains of oscillations produced by the author's vibrating wire interrupter led to difficulties in the mathematical discussion of cable problems which were vastly greater than those met with in the sine wave problem, for which alone the currently used formulæ were correct. He asked how far experimental results obtained with damped trains disagreed with the sine wave formulæ. For practical purposes the damped trains used by the author were a better imitation of speech sounds than pure sine oscillations. He asked if the indication of a barretter when used with ordinary speech sounds or with damped trains corresponded strictly with the volume of sound.

The Author, in reply to Dr. Russell's remarks about the diminution of the attenuation constant, remarked that, by loading, both advantages referred to were obtained. The limit was determined in practice by the volume of sound transmitted, and not by articulation conditions. In reply to Mr. Campbell he said he was working with an attenuation of 1·5 per cent., and the sending current was 3 or 4 milliamperes. The apparatus would work quite well up to frequencies of 1,500. In reply to Mr. Whalley, he said that increasing the current in the circuits up to 0·1 ampere would have no effect on the inductances. In reply to the remarks of Dr. Eccles, the barretters used were measuring current and not energy. The current received was a most important factor in determining the volume of sound transmitted.

STREET LIGHTING IN WESTMINSTER.

In our last issue we gave an account of the meeting of the Westminster City Council, at which a report of the Works Committee recommending that the tenders of the Gas Light & Coke Co., for street lighting, should be accepted was adopted. As this report contains some figures of interest regarding the cost of lighting we reproduce that part of it herewith. After mentioning the districts in which the new scheme of lighting is to be carried out the report continues:—

Competitive tenders were therefore obtained from the Gas Light & Coke Co. and the several electric light companies for the *installation* of lighting units of different powers—viz., 90, 180, 300, 1,800 and 3,000 candles, the Council being placed in a position to select one or other of the lighting units, according to the needs of each class of street as may be determined by considerations of widths, conditions of traffic, &c. For the *supply* of gas or current, as the case may be, to these several units and for general *maintenance*, further tenders were obtained, any of which may be accepted for a term of 5, 10 or 15 years at the option of the Council.

It should be pointed out that the basis on which tenders were invited was so much light for a given number of hours per annum, and as a given candle-power, for instance 90 or 3,000 candles, has exactly the same value whether produced by gas or by electricity, all we have had to consider has been the cost of installation, and also the annual cost for the different units.

The classification of streets for lighting purposes, another important matter, will be for the council to decide at a later date upon a further report from us; but whatever classification is adopted will not affect the *comparative* costs of the different methods of illumination. It may, however, be stated that in settling the specification, certain streets of importance were named in each district in which the council might, as foreshadowed above, wish to effect greater improvements by the adoption of higher lighting power units. Certain experimental installations have been set up in Victoria-street and elsewhere at the expense of the competing companies, which constitute a practical and valuable exhibit of different forms of lighting in juxtaposition; and besides viewing these exhibits we have made a tour of inspection of the different systems now in use in Westminster, and have extended our inspection to the City of London, where (in Fleet-street) a notable example of gas lighting is set up.

Table I.—*Showing Existing Units of Light under Contracts terminating in* 1910.

4	Do. do. ...	1,656 c.p., at £17. 0s. 0d.				

Table I. shows the existing units of light under contracts terminating in 1910, and with which therefore this report deals. It will be seen from this table that the districts now being dealt with are the districts lighted by gas together with the district lighted by 71 arc lamps by the St. James's & Pall Mall Electric Light Co. The electric lighting in the Strand district and the electric lighting throughout the parish of St. George are not affected.

The present lighting in these districts is as follows:

Strand District Electric Lighting Contract, terminable in 1913 or 1920 at option of Council:—

121 arc lamps, average c.p. 614, at £27. 18s. 3d. (average) each per annum.

3 flame arc lamps, average c.p. 1,270, at £27. 13s. 4d. (average) each per annum.

St. George's Parish Electric Lighting Contracts:—

(*a*) Terminating in 1913—

5 flame arc lamps, average c.p. 1,573, at £14 each per annum.

(*b*) Terminating in 1931—

957 arc lamps, average c.p. 449, at £21. 2s. 5d. each per annum.

216 lamps (various) at £3. 9s. 0d. (average) each per annum.

Table II. deals with the first cost—*i.e.*, installation—and the only remark to be made upon this is that the gas company offer to spread any installation cost over the contract period without interest, thus further increasing the difference in the cost of installation which a glance at the table will show exists between gas and electric light tenders.

Table III. deals with annual cost—*i.e.*, supply of various units of light, together with lighting, extinguishing, maintenance, &c.

The above quotations in Tables II. and III. for *identical units of lighting* need little comment. The Gas Company's tender for installation (Table II.) is very much below the electric supply companies' tenders. For lighting and maintenance (Table III.), that is to say, the annual charge, the same marked difference in cost is shown in favour of gas, light for light. Not to labour the point too much, one comparison only is made. Worked out, the difference in cost (Table III.) for a term of five years for the five units specified is 76·99, 77·77, 80·77, 33·87, and 29·54 per cent. respectively in favour of gas. That is to say it would cost these percentages more for maintenance year by year if electricity were preferred to gas, and, for such extra cost not a single candle power better lighting would be obtained.

FARADAY SOCIETY.

At the meeting of the Faraday Society held on Tuesday, April 5th, at the Institution of Electrical Engineers, Dr. J. C. CAIN in the chair, the President, Mr. JAMES SWINBURNE, referred to the sad death of Prof. Richard Abegg, as a result of a balloon accident on April 4th, by which the Society then lost one of its most distinguished members. He moved that a vote of condolence be transmitted to Frau Abegg on behalf of the Society. This was seconded by Dr. V. H. Veley, and carried in silence. After Mr. W. P. Dreaper had read a Paper entitled "Nature of the Action of Dyeing," Prof. W. W. HALDANE GEE and Mr. W. HARRISON contributed a Paper on

"The Electrical Theory of Dyeing."

The literature relating to the causes of dyeing reveals great differences of opinion as to the physical and chemical phenomena involved. The basis of the electrical theory is that when any two bodies are placed in contact they are oppositely electrified. In the case of tinctorial chemistry one of the bodies is a non-conducting solid and the other a liquid. There does not seem to be any direct method of obtaining the value of the P.D. between such bodies. The authors avail themselves of the classic theory of von Helmholtz, which enables the P.D. between a liquid and a porous diaphragm to be deduced. This may be done in four different ways: (1) By measuring the rate of flow of the liquid through a diaphragm of the substance under electrical stress (electrical endosmose). (2) By measuring the mechanical pressure obtained by electrical endosmose. (3) By determining the speed of the solid in the form of small particles when immersed in the liquid under electrical stress. (4) By measuring the difference of electrical pressure between the two sides of a diaphragm when the liquid is filtered under mechanical pressure.

The authors have determined the nature of the charge on the particles in suspension and in colloidal solution, and find that in water all basic substances are positive, the hydrochlorides of basic dyes positive, all acid substances negative, and most neutral substances negative. They find the speed of the particles under electrical stress to be of the order 20×10^{-5} cm. per second, per volt, per centimetre. Negatively charged particles attain their maximum speed at about 40°C. By using method (4), the authors find the approximate value of the contact difference between fibres and water to be:—

Cotton	0·06 volt.
Silk.....	0·22 ,,
Wool	0·90 ,,

The influence of temperature shows a maximum charge at about 40°C., and a minimum at about 80°C. The electrical theory may be stated as follows: Suppose the dye to be basic and represented by $n-P$, where n is a small negative ion and P a large positive basic ion. These ions will be free, and when wool or silk is placed in the solution the basic ions will be attracted by the negatively charged fibres, and be fixed by some process which is not yet properly understood. The small ions will combine with the H ions present in the so-called double layer. If inorganic electrolytes are also present in the solution, and are of an alkaline nature, they will tend to make the fibre still more negative, and will assist the process of dyeing.

In the case of acid dyes they deal with substance of the nature $p-N$, where p is now a small positive ion and N a larger negative ion. In this case acid is either added to the bath or the fabric has been previously boiled with acid. In each case the fibre takes a positive charge. The result will be that N will be attracted by the positively charged fibre, whilst p will form a salt in the vat. A strong confirmation of the theory is afforded by the amount of absorption of dye stuffs at different temperatures. Brown has shown that with basic colours the maximum amount of dye stuff is absorbed at about 40°C. and the minimum at about 80°C. The authors' results show that the maximum negative charge is attained at about 40°C. and the minimum at about 80°C.

Ultramicroscopic examination of pure benzopurpurine is given after filtration, and the solution was found to contain no visible particles in the ultramicroscope. An experiment is given on the destruction of the colloidal nature of an impure sample by heating the solution. Important analogies are given between the laws of contact electricity, colloidal coagulation, dyeing and capillary ascension, and the effects of temperature are discussed.

In the course of the joint discussion which took place on the two Papers,

Dr. W. C. McC. LEWIS (communicated) drew attention to the importance of the work of Prof. Gee and Mr. Harrison, especially their beautiful method of showing the gradual transition from the charged colloidal state to the state of a non-electrolyte in true crystalloidal solution, as well as the remarkable temperature effects which the P.D. of the particles undergo. Had the authors determined the P.D. water/glass? This was of great importance in endosmotic work. The potential gradient at the surface of the particles could be shown to be of the order 10^{-6} volts per centimetre. Could this be withstood by water without something analogous to sparking taking place? It was possible that the high values obtained by Lodge for the velocity of the hydrogen ion as measured in a set gelatine solution were really owing to the velocity with which the solvent as a whole carried the hydrogen ion along with it as it was impelled through the network of the jelly by the external E.M.F. Hydrolysis would seem to complicate the simple electrical theory, because the conditions of temperature and dilution under which dyeing took place were favourable to hydrolysis as well as to ionisation.

Dr. V. H. VELEY remarked on the peculiar maxima values obtained by Messrs. Gee and Harrison at 40°C. Remarkable effects occurred at this temperature in many physical and chemical actions, such as the evolution of carbonic acid from leaves, or the coagulation of muscle and nerve stuff.

Dr. H. BORNS drew attention to some recent ultramicroscopic work in which had been observed the movements not only of colloidal suspensions, but of ions, or groups of ions, themselves.

Mr. W. P. DREAPER, commenting on the Paper of Messrs. Gee and Harrison, showed that in many cases of dyeing the conditions favourable to electrolytic dissociation were not obtained. The dissociation of the dye salt into ions and transference of one of these to the fibre area required further confirmation. Possibly the function of the electrical action was merely one of concentration of the dye within the fibre area rather than controlling the true dyeing action. Anyhow, there were many difficulties, which the speaker instanced, in the way of accepting the electrical theory so far as the fixation of the dye was concerned.

Dr. E. FEILMANN also mentioned some facts that seemed difficult to reconcile with the electrical theory, such as that many dyes were used in the form of paste, and not in solution at all, and that a large class of fast dye stuffs formed true colloidal suspensions. There were, he thought, a great variety of dyeing processes.

Mr. W. R. COOPER asked whether basic dyeing would take place if a positive charge were impressed on the fabric; if not, support would be lent to the electrical theory.

Mr. F. J. FARRELL quoted instances in which the splitting of the ultimate fibre, without any chemical alteration, prevented the dyeing action in the case of silks. He agreed with Mr. Dreaper that the maximum effects found at 40°C. bore no relation to actual results in practice. As a rule, no good results were obtained at less than 95°C.

The CHAIRMAN was of opinion that many of the phenomena observed in dyeing could be explained merely from a mechanical point of view; the effect of temperature was an instance of this. At the same time, the electrical theory might be useful in explaining the initial attraction between the dye and the fibre, even if it did not explain the fixing, which perhaps was to be attributed to the ultimate attraction of matter for matter, namely, cohesion.

High Tension Electrical Transmission in Italy.—According to "The Times Engineering Supplement" the equipment of an electrical power station to utilise the water power of the river Pescara, in the neighbourhood of Torre del Passeri, is now in progress. The plant will comprise four three-phase alternate-current generators, each of 8,200 to 9,000 H.P., delivering current at from 6,000 to 6,600 volts, with a frequency of 42, when running at 420 revs. per min. These sets will be direct coupled to water turbines. There will also be two exciter machines of 400 kw. each, delivering current at 220 volts when running at 600 revs. per min.; and seven single-phase alternate current transformers of 3,600 k.v.a. each, six of which are combined in two three-phase sets (star-connection), while the seventh serves as a stand-by. These single-phase transformers are calculated for a ratio of 6,000/46,200 or (with constant output) 6,600/51,000 volts, and are insulated for 90,000 volts. The linked-up phase tension at the secondary terminals is 80,000 and 88,000 volts respectively. The whole of the electrical energy generated at the station is to be conveyed through a double line about 125 miles long to Naples, where it will be reduced in a substation partly to 5,300 volts for the City of Naples and partly to 27,000 volts for transmission to Torre-Annunziata.

The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, aoroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. B. Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-seventh issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for April 1.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

With this week's number of "THE ELECTRICIAN" is issued (Gratis) the Index to Vol. LXIV. This includes the Index to the "Industrial Supplement."

Complaints of non-receipt should be promptly made to the Publisher.

READY APRIL 29th.—Vol. LXIV. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXIV. are now ready, price 2s.: post free, 2s. 3d.

STREET LIGHTING.

Since the early days when electrical energy was first produced by means of a dynamo, arc lamps have always been in favour for the illumination of important public thoroughfares and open spaces. Originally this was due, perhaps, partly to the fact that they provided a very high candle-power and good illumination, coupled with a low cost per candle-power-hour. The result was that for a long time public lighting by electricity was largely confined to streets where more than an average illumination was required. With the development of electricity supply electrical engineers naturally turned their attention to extending the field of electric lighting into those streets where smaller units of light were required. Although the carbon filament lamp was able to compete satisfactorily with the flat flame gas lamps, the extensive adoption of incandescent gas mantles limited, in the majority of cases, the extension of electric lighting into side streets. For many years, however, the 10-ampere open type arc lamp held the field in the main streets, enclosed arcs, although requiring less attention and reducing the cost of carbons, being generally considered scarcely as efficient. The introduction of the flame arc came at an opportune moment, for improvements in gas lamps, as regards efficiency and the possibility of obtaining large units, were

Digitized by Google

threatening to bring these lamps into effective competition with the electric arc. The flame lamp has, however, given electrical engineers an effective weapon to repel the attacks of the gas undertakings, attacks which, during the past year or two, have shown increasing keenness, due probably to the growing evidence of the steady inroads made by electricity into those fields hitherto supposed to be the strongholds of gas.

The advent of metal filament lamps a year or two ago was quickly recognised by electrical engineers as affording an exceptional opportunity for extending the field of electricity in public lighting; and with what success may be judged from our Annual Tables and from the reports in our columns from week to week of the substitution of electricity for gas. The full effect of the metal lamp is, however, only now becoming fully apparent. At first these lamps were only made in units of from 20 c.p. to 50 c.p., but during the past year there have been placed on the market lamps ranging from 100 c.p. up to even 1,000 c.p., and, as will be seen from another column of this issue, these high candle-power lamps are giving excellent results, both as regards life and efficiency. So much is this the case that they have been substituted in many cases for arc lamps, and further developments in this direction are foreshadowed.

As compared with an arc lamp, a glow lamp has several advantages. Of these may be mentioned less attention and the absence of "trimming," the possibility of using reflectors more effectively, the absolute steadiness of the light, and the ease with which the candle-power can be changed if desired. A further point is that 500 c.p. lamps located, say, every 30 yards, might give a more desirable illumination than 2,000 c.p. lamps placed every 60 yards. Each case, however, must, of course, be decided on its merits, and the higher efficiency of the arc lamp offset against the advantages which can be put forward in support of the glow lamp. There is no doubt, however, that considerable attention is now being paid to the claims of the high candle-power metal filament lamp, which bids fair to play an important part in the future in the problem of street lighting. Perhaps these lamps will, to some extent, oust arc lamps from their hitherto unassailable position, though we think the flame lamp is still likely to hold its own where a large space has to be illuminated at a low cost, or where a high degree of illumination is required.

In regard to the competition between gas and electricity in street lighting, the near future promises to be of the first importance. It is well known that the Corporation of London have been investigating for some time the merits of the two illuminants. The Corporation of Westminster also have the matter under consideration, as will be seen elsewhere. There is, of course, some difficulty in the partisans of either side forming a calm judgment in such cases, but there is one point to the disadvantage of gas that is not as fully realised as it should be, although reference is often made to it. We refer to the falling off in candle-power of incandescent mantles. For example, a mantle consuming 4¼ cubic ft. per hour gives 82 c.p. to 85 c.p., and it is stated that such mantles do not depreciate appreciably with 200 hours' use. Actual tests do not bear out this view, and in support of this statement we may mention some tests which were carried out not so very long ago by a well-known firm who are certainly not biased in favour of electricity. In the case of 58 single-burner lamps they found that the maximum candle-power was 86 and the minimum 26, with an average of 49. In the case of 36 two-burner lamps a maximum of 111 c.p. was obtained with a minimum of 58 and an average of 76. In the case of six three-burner lamps the maximum was 150 c.p., the minimum 89 and the average 115. In this respect electricity is usually at a disadvantage when competing with gas, because quotations are given with metal filament lamps for a standard of illumination which will not depreciate, whereas the quotations for gas generally involve the assumption that depreciation is non-existent. It is time that the public realised that illumination obtained from gas mantles does depreciate, or if it is maintained at a given value, money is required for the purpose.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Wireless Telegraphy and Telephony. By A. E. KENNELLY. (London: T. Fisher Unwin.) Pp. 271. 4s. nett.

This is a book that can be read and appreciated by anyone who has had just a little practice in the study of physics; it gives a survey of the principles underlying wireless telegraphy and "wireless" apparatus, and strictly avoids descending to details. The exposition of principles is accomplished carefully and clearly and usually with unimpeachable accuracy. We are glad to note that the author adopts Oliver Heaviside's pellucid method of explaining the formation of electromagnetic waves by the oscillation of a charge on a vertical straight antenna: it is strange that this, the best (and oldest) of all ways of discussing wireless waves has been singularly neglected by English authors. Unfortunately, in the present case, the diagrams concerned with these matters are even worse than the bad diagrams scattered through the rest of the book.

A principal and striking feature of Dr. Kennelly's book is the very complete omission of historical matter. This has its advantages and disadvantages. Among the latter we may put the fact that the reader finishes the volume without the faintest notion of the order of development of this branch of engineering. This feature is pushed so far that the reader is left in absolute ignorance of the names, even, of the engineers and inventors who have counted most in the technical progress of wireless telegraphy. Indeed, we noticed the name of only one inventor, Fessenden, in all the 280 pages; and thus the author can boast the distinction of having written a work on wireless telegraphy without even mentioning the names of, say, Lodge and Marconi. Except for these blemishes the outlines of wireless telegraphy are excellently presented, the writing displays considerable literary skill and taste, and the book is very suitable for those who desire no other contact with wireless telegraphy than an intellectual one.

W. H. ECCLES.

Drawings for Medium Sized Repetition Work. By R. D. SPINNEY. (London: E. & F. N. Spon, Ltd.) Pp. x.+91. 3s. 6d. nett.

This book is intended for engineers who supervise the making of drawings for such parts of a machine as are made in quantity. The illustrative examples refer to motor-car practice, but the underlying principles can be applied to any class of work. There are many details in the book which are open to criticism, but on the whole it is an excellent attempt to indicate how to make, and what ought to be thought of in the making of, drawings for repetition work. The writer betrays a sound knowledge of shop practice throughout, and gives many useful hints to the designer who has had little shop experience. Apart from manufacturing considerations, the design of machine parts is not dealt with.

Digitized by Google

Chapter I., on drawings generally, includes a set of model rules for a drawing office.

In Chapter II., on standard lists, it is evidently a mistake to give elongation in tons per square inch and to call a steel having 45 to 55 tons per square inch mild. In giving the elongation it would be an improvement if the author would include the diameter of the test piece as well as its length.

In the chapter on indexes it is unfortunate that card indexes are not given more consideration, and the method of recording alterations "in a book" seems clumsy compared with the methods used by many large firms.

Chapter IV., on tolerances and allowances, and the following one, on dimensioning, are perhaps the most useful in the book, and contain some valuable information. The press fit allowances in particular are the most reasonable which we have seen published. In Chapter VI., on designing, the statement "material cannot be called saved which is cut away in the form of scrap," cannot surely be applied to, say, copper scrap from a punching machine; and in the concluding chapter, on drawing office routine, the statement that general arrangement drawings need only be dimensioned as regards centres, &c., contradicts rule 27. R. L.

STREET LIGHTING BY HIGH CANDLE-POWER METAL LAMPS.

In a recent issue we commented upon the increasing use of high candle-power metal filament lamps for street lighting, and in connection with most of the work which has already been done in this field we associated a well-known make of tungsten lamp. We remarked upon the satisfactory emergence of this lamp from the experimental stage and its practical value as an illuminant for streets and thoroughfares previously only lighted by ineffective and more costly methods. Our remark that this particular make of lamp appeared to be the only one which had emerged from the experimental stage elicited a certain amount of criticism. As we hold no brief for any particular lamp, and are only too pleased to see the spread of electric lighting now rendered possible, we have made a number of inquiries and have received replies from a number of central station engineers who have been good enough to supply us with interesting particulars. In what follows we reproduce this information, and we are thus able to indicate pretty fully how the position at present stands:—

Mr. H. Tomlinson-Lee, of Wimbledon, is in a position to speak with authority on the subject of street lighting, since the whole of the public lighting of that borough is carried out by the electricity department. In fact, gas lamps disappeared from the streets in a comparatively distant past; and it will probably come as a surprise to many electrical engineers to learn that at that time oil lamps displaced the gas lamps, being themselves in turn displaced by electric lamps. For many years the public lighting has now been carried out entirely by electricity, and to judge by the satisfaction evinced by the Council and ratepayers at the present system of illuminating the streets, electricity in this locality should long continue to reign supreme.

To give an idea of the extent of the street lighting at Wimbledon, we may mention that at the present time there are 91 flame arc lamps, of the Foster and Excello types, and 1,136 metal filament lamps. These latter are in all cases Osrams, and comprise 44 of 300 c.p. (330 watts) and 1,092 of 50 c.p. (55-63 watts).

It is interesting to notice that special mains have been laid for supplying the street lighting, and duplicate trunk mains are run from the power station, one of these trunk mains serving as a standby. Switching-on individual lamps or circuits is in this way rendered unnecessary, the whole of the street lighting being controlled simultaneously from the works. It will be understood that it would be impossible, or at any rate inadvisable, to switch the whole of this load on to the ordinary generating plant simultaneously, so the following arrangement has been adopted. The trunk main for the street lighting is connected on to special 'bus-bars, and a special machine is run up on the load. When the normal pressure has been reached the special 'bus bars are paralleled with the main 'bus bars, the generators being, of course, first synchronised, and the street lighting load can then be taken charge of by the main plant, the special machine being shut down, if desired.

Considering now more in detail the street lighting by metal filament lamps, it may be mentioned that the 300 c.p. Osram lamps have been substituted in most cases for enclosed arc lamps, and the existing arc lamp columns have been utilised. This results in the lamps being about 18 ft. from the ground,

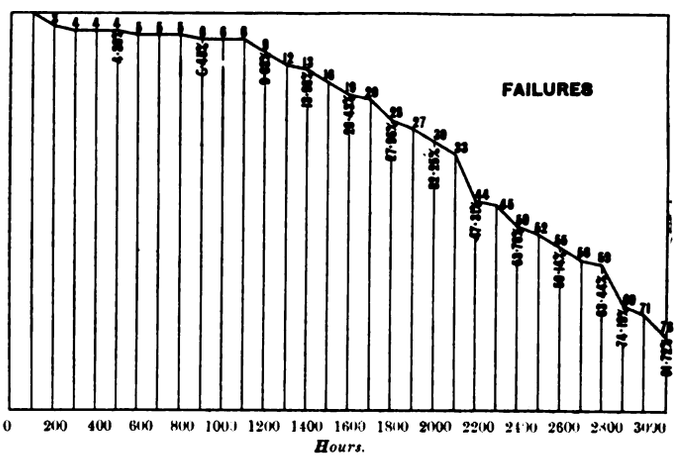

Fig. 1.—Chart showing Test on 93 Osram Lamps installed on Sept. 15, 1908.

(The total number and percentage of failures are recorded every 100 hours.)

and the light is distributed over an extensive area. To increase the efficiency of the distribution, Holophane reflectors have been fixed over the 300 c.p. lamps. Judging by the illumination of the surface of the roads, the lighting so obtained leaves little to be desired, and on inspecting the street lighting last week we were struck by the excellent results obtained, the illumination provided by the 300 c.p. lamps far exceeding what we had anticipated. A feature of the street lighting by these large metal lamps is the absolute steadiness of the light, this being, undoubtedly, a great recommendation; and the fact that practically no attention is required, should result in bringing them into increasing favour with central station engineers.

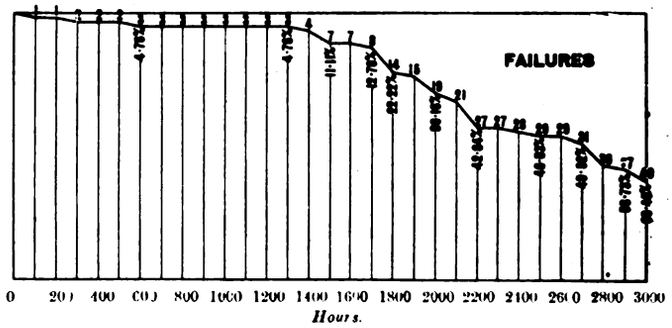

Fig. 2.—Chart showing Test on 63 Osram Lamps installed on Sept. 29, 1908.

(The total number and percentage of failures are recorded every 100 hours.)

As to the spacing of the lamps, the distance apart of the 300 c.p. Osrams averages about 100 yds.; but it varies from 70 yds. to, say, 120 yds. It is obvious, of course, that a fixed distance is inadvisable, since, given a certain latitude, the lamps can, with advantage, be arranged to come at street corners, so illuminating most effectively the positions where a good illumination is necessary.

The Osram lamps of smaller candle-power—viz., 50 c.p.—are used for side street lighting, and are situated about 60 yds. or 70 yds. apart, at a height of 12 ft. 6 in. above the road. In all cases the existing lanterns and columns, which had done duty in the days of gas and subsequently of oil, have been

Digitized by Google

utilised. No reflectors or special fittings are necessary, the lamps being suspended vertically downward from the rubber-covered wires. It may here be mentioned that a separate service is laid for each lamp column, rubber-covered wires being employed. Before Osram lamps were adopted, two 16 c.p. carbon filment lamps were fixed in each lantern.

From what has been said above it will be evident that each lamp is an independent unit, and the failure of any one lamp does not affect other lamps. The pressure of supply is 220 volts in the case of the incandescent lamps, whilst a separate transformer is installed at the base of every arc lamp, these latter taking about 550 watts each.

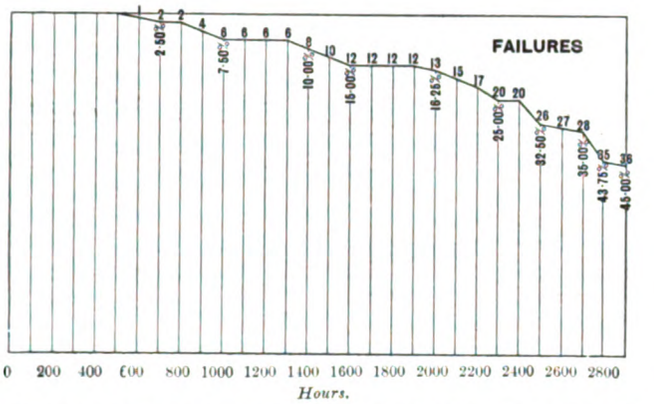

FIG. 3.—CHART SHOWING TEST ON 80 OSRAM LAMPS INSTALLED ON OCT. 8, 1908.

(The total number and percentage of failures are recorded every 100 hours.)

A point concerning which electrical engineers are most anxious to obtain information is the life of metal filament lamps employed for street lighting. We are, therefore, pleased to be able to publish typical results obtained at Wimbledon during the last year or two. It will be seen from Figs. 1, 2, 3 and 4 herewith that the records go back to September, 1908. An interesting system of keeping records of the life of lamps has been adopted by Mr. Tomlinson-Lee. Thus, considering Fig. 1 (which refers to a batch of 93 Osram lamps installed on September 15, 1908), at each 100 hours the total number of lamps which have failed is shown by the respective figures, whilst against the curve the percentage of failures is recorded. Thus, after 1,100 hours it will be noticed that 6 lamps, or 6·45 per cent. of the total, had failed; after 2,000 hours 30

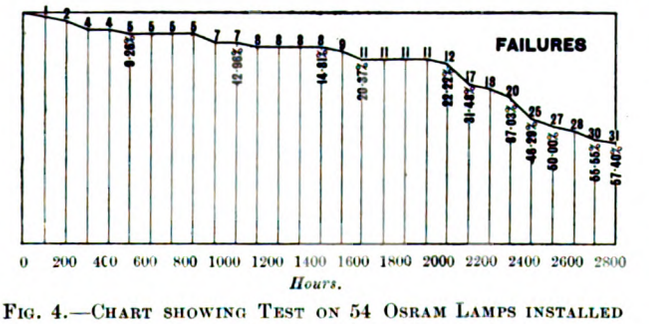

FIG. 4.—CHART SHOWING TEST ON 54 OSRAM LAMPS INSTALLED ON OCT. 13, 1908.

(The total number and percentage of failures are recorded every 100 hours.)

lamps, or 32·25 per cent.; whilst after 3,100 hours 76 lamps had failed—that is to say, at the conclusion of the chart 17 lamps, or over 18 per cent. of the total, were still in use.

Again, Fig. 2 shows a similar record for 63 Osram lamps installed on September 29, 1908. From this it will be seen that no less than 23 lamps, or about 37 per cent. of the total, were still burning after 3,000 hours. Fig. 3, which relates to 80 Osram lamps installed on October 8, 1908, shows a wonderful record of life, 55 per cent. of these lamps being in use after 2,900 hours; whilst of the batch of lamps referred to in Fig. 4, 43 per cent. were still alive after burning 2,800 hours.

Great attention has been paid by Mr. Tomlinson-Lee to facilitating the keeping of records of the life of lamps, and as, owing to the whole of the street lighting being switched on simultaneously from the electricity works, it is easy to keep a record of the exact period during which the lamps are lighted, a chart has been prepared which enables the life of a lamp to be at once read off. We may mention that the street lighting is divided into districts, for each of which a lamp attendant is responsible. Each attendant devotes an hour or two every evening to inspecting the lamps in each district, and in the case of any lamp having failed, the attendant usually replaces the lamps immediately, climbing up the lamp pillars in the case of the short columns in the side streets, so as to minimise extinctions. Payment is made to the police for reporting extinguished lamps, but we understand that the lamp attendants are so attentive that the police make few claims.

The lamp charts given above refer entirely to Osram lamps of 50 c.p. Complete charts have not yet been made for the 300 c.p. Osrams, but Mr. Tomlinson-Lee informs us that the 300 c.p. lamps are giving even better results than those mentioned above for the lower candle-power lamps, and he is enthusiastic in his praise of Osram lamps of all candle powers. It is worth mentioning that experience at Wimbledon shows that the useful life of an Osram lamp is determined solely by breakage, the blackening, except in cases where lamps fail at an early stage of their life, being unnoticeable.

The following particulars of the cost of street lighting at Wimbledon may probably prove of interest. The cost of current, including all capital charges of the distributing system and lamps, &c., to March 31st, was approximately, £4,700 for 502,420 units metered on the trunk mains at the station, and the cost usually works out at about 2¼d. per unit. In addition, the attendance, repairs and renewals together amount to about £1,800 per annum.

In conclusion, we may mention that Councillor Dudley Stuart, vice-chairman of the Electricity Committee, has taken a very keen interest in the question of street lighting by metal filament lamps, and has devoted a considerable amount of time to its development at Wimbledon. It will be remembered that Mr. Stuart made a valuable contribution to the discussion on Mr. E. E. Hoadley's (Maidstone) Paper on "The Influence of Metallic Filament Lamps on the Electrical Industry and on Street Lighting" at the I.M.E.A. Convention at Manchester last year.

Turning now to other districts, we have been favoured with a number of interesting letters, the substance of which we give below:—

Mr. G. G. BELL, of Hammersmith, informs us that his Council are using Osram lamps. Fourteen 400 c.p. lamps were fixed on November 4th last, and the average life of the seven which have failed was 1,360 hours, whilst the remaining seven are still burning after about 2,500 hours.

Mr. P. E. RYCROFT, electrical engineer to Heston and Isleworth District Council, states that about 80 100 c.p. 250-volt Meta lamps are in use by his Council, and have given good results. Experiments are, however, being made with other makes of lamps, including the "Z" lamp, the Mazda lamp, Osrams and the "Onewatt" lamp. The average life of the 100 c.p. Meta lamps during the last 12 months was about 1,700 hours.

Mr. A. J. FULLER, of Fulham, informs us that 400 c.p. metal filament lamps have been tried in Fulham; but whilst they are satisfactory from the point of view of life, Mr. Fuller is of opinion that a better light is obtained by fixing a cluster of three or five smaller lamps aggregating the same candle-power. Osram and Aegma lamps of 75 c.p. have proved very satisfactory from a maintenance point of view.

Mr. W. C. P. TAPPER has installed six 100 c.p. Osram lamps in Wentworth-street, Stepney. His opinion is that the street is very well lighted. The average life of the lamps is 1,267 hours.

Mr. TREVOR DUESBURY, of Sutton Coldfield, mentions that the Corporation have replaced six enclosed arc lamps by fittings each containing four 100 c.p. tungsten lamps, and the light is considered to be at least equal to that of the arc lamps

Digitized by Google

displaced. It is proposed eventually to replace the whole of the arc lamps in this way. Although really outside the present subject, it is interesting to learn that at Sutton Coldfield there are also 209 posts carrying lanterns each containing two 32 c.p. or 50 c.p. lamps of Osram or Sunbeam manufacture, and the maintenance costs are said to be very satisfactory.

Mr. S. Cameron Gibson, of Nuneaton, has sent us some very interesting information in regard to street lighting by high candle-power metal lamps. The main streets at Nuneaton are at present lighted by means of open-type arc lamps, in series of 10 lamps. These lamps have been in use for some six or seven years, and consequently it was felt that steps ought to be taken to bring the lighting of the main streets up to date. The Committee were so pleased at the effect obtained with an experimental fitting containing five 100 c.p. metal filament lamps, erected in place of one of the arc lamps, that they gave instructions for the whole of the existing arc lamps to be replaced by clusters of metal lamps, and this is now being done. Mr. Gibson informs us that he is obtaining a life of over 2,000 hours with the 50 c.p. Osram lamps used for side street lighting, and that the 100 c.p. lamps have not been installed long enough for him to give particulars of their life, but he anticipates obtaining a life of 2,000 hours with these 100 c.p. lamps, among which are some of "Stearn" manufacture. On the basis of a life of 2,000 hours, Mr. Gibson estimates that the cost of renewals will work out at about two or three times the cost of renewals with arc lamps, but a considerable saving, more than sufficient to compensate for these renewals, will be obtained in labour. It must also be remembered that substantial reductions in the price of high candle-power metal lamps are probable at an early date. Mr. Gibson also mentions that, in his opinion, it is preferable to use a number of low candle-power units rather than one lamp of, say, 500 c.p., in order to lessen the risk of a standard being in darkness.

Mr. S. J. Watson, of Bury, mentions that he is experimenting with high candle-power metal lamps, and that it is not unlikely some of the existing arc lamps may be replaced by groups of these metal lamps.

Mr. W. H. Miller, of Fleetwood, states that of the 350 electric street lamps in that town, two-thirds have already been changed from carbon to metal filament lamps. The results have been so satisfactory that it has been decided to change over at once the remaining third of the lamps. The candle-powers of the lamps used are 200, 100 and 50, and when the change-over is complete 60 per cent. of the lamps will be Osrams, 20 per cent. "Auriga" and 20 per cent. "Effesca." Mr. Miller is obtaining very good results with these lamps.

Mr. J. A. Gow Russell, of Dalkeith (the Electric Supply Corpn.), replies that 50 c.p. and 100 c.p. Osram and Auriga lamps are used in Dalkeith. They are giving satisfaction in spite of a great deal of vibration, the 50 c.p. lamps being attached to arc lamp pillars fitted with lowering gear.

Mr. J. Pilling writes that at King's Lynn there are between 600 and 700 Osram lamps of 50 c.p. and 100 c.p. in use for street lighting, and he states that the 100 c.p. Osrams are particularly satisfactory, burning almost indefinitely without replacing. The filaments in the 50 c.p. lamps are found to be more liable to fracture than those of higher candle-power.

Mr. C. Furness, of Blackpool, mentions that he has recently installed about half-a-dozen cluster fittings, each made up of eight 50 c.p., and one 600 c.p. lamp. Osrams are used almost entirely in Blackpool for street lighting, in 32, 50 and 100 c.p., at 200 volts, and the average life is found to be about 1,000 hours, though in a number of cases the lamps have burnt as long as 2,000 hours.

Mr. C. A. Blascheck replies that a few high candle-power Osram lamps have been installed at Canterbury for street lighting, and at present he has no fault to find with them.

Mr. A. D. Chalmers, of Gillingham (Kent), states that high candle-power Osram lamps have been used for street lighting in Gillingham, but only for the last two months, so that the results are hardly yet ascertainable. Osram and Cryselco metal lamps of 50 c.p. and 32 c.p. have been used, however, for side street lighting for about two years. It is interesting to note that Mr. Chalmers recently photometered about half a dozen of the incandescent gas lamps in use for street lighting, for which the local gas company claim 140 c.p., and he obtained an average figure of only 39·4 c.p., the highest being 47·5 and the lowest 36. A Harrison flicker photometer was used in making these tests.

Mr. S. L. R. Price, of Pembroke (Co. Dublin), substituted, some six months ago, high candle-power metal lamps for two circuits of arc lamps (nine lamps on each circuit), of which the cost of repairs after nine years' running had become considerable. In place of each arc lamp a cluster of five 100 c.p. metal lamps was fitted, the total cost of 17 clusters amounting to about £120, including an independent service to each post. The eighteenth post was allowed to remain as an arc lamp for special reasons. It may be mentioned that the cost of the change was approximately the same as if the existing lamps had been replaced by modern arc lamps. At the start, Osram, Sunbeam and G. M. Boddy & Co.'s lamps were installed. Equally good results were obtained with the Osrams and Sunbeams, but, due to breakages in transit and the consequent delay caused in obtaining replacements, it was decided only to use Osrams, as these could be obtained locally. So far the cost of renewals has worked out practically equal to the cost of carboning the arc lamps previously installed, but it has been possible to dispense with the services of an arc lamp trimmer, thereby saving about £65 per annum, in addition to which there has been considerable saving in repairs. Mr. Price draws attention to the fact that at the end of every 9 or 10 years the arc lamps would require to be replaced, whereas with metal lamps no such question arises.

Mr. C. M. Shaw, of Worcester, informs us that 50 c.p. and 100 c.p. metal lamps, mainly Osrams, have been fixed in pairs on the tramway poles of all routes not hitherto illuminated by arc lamps or small electric standards. General satisfaction is expressed with the lighting given by two 50 c.p. lamps on each pole, and the general distribution of light, Mr. Shaw considers, is much superior to any other he has seen for the same amount of energy consumed.

At Horsham, the largest metal lamps used for public lighting are 63-watt Osrams, but Mr. J. B. Morgan's reply to our letter draws attention to several interesting features. The bulk of the street lighting at Horsham is by 23 c.p. Tantalum lamps in series, but at prominent street corners two high-voltage tungsten lamps are installed. His experience with Tantalum lamps is uniformly satisfactory, the average life of these lamps being about 1,600 hours; but with tungsten lamps the results are far from uniform, probably due to local circumstances, though precisely what causes the premature failures in certain situations is at present unknown, for all makes of lamps tried on these particular posts give the same inferior results. As the lamps are under-run 5 per cent., the failures are not caused by excessive voltage at these points.

THE DIRECT MEASUREMENT OF MEAN SPHERICAL CANDLE-POWER BY DIFFUSION METHODS.*

BY W. E. SUMPNER, D.SC.

Although the Ulbricht globe yields good results, there are some sources of error. Its accuracy is dependent on at least four assumptions. (1) The inner surface must reflect light of all colours equally well, and the reflecting power should be high. (2) It is assumed that there are no surfaces within the globe which absorb or reflect light. This cannot be quite true in practice. (3) A third assumption which is well understood, is that the surface of the Ulbricht globe reflects light by diffusion only. (4) It is assumed that the photometer window transmits light by diffusion only—that is, it is assumed that none of the rays pass straight through it, as would be the case with transparent glass. The material used for this window must be most carefully chosen, for unfortunately any translucent substance like milky glass transmits light partly by diffusion, and partly by direct transparency, and it may quite easily happen that the amount of light leaving the sphere through the photometer window is quite as much

* Abstract of a communication to the Illuminating Engineering Society.

Digitized by Google

due to transparency as to diffused transmission. In such a case the effect on the photometer measurement would be serious, because the light received would consist of two parts following different laws. In 1892 I gave a proof of the following statement, which forms the basis of the action of the Ulbricht globe. "If any complete (or if any portion of a) spherical surface be illuminated in *any* manner by the *direct* rays of a combination of light sources, the actual illumination I will exceed I_0 the initial illumination by a *constant amount* all over the sphere, owing to the reflective action of the surface."

This theorem is remarkable for two things—for the ease with which it can be proved and for its extreme generality. It does not matter how uneven the candle-power of the light is, or where it is placed. It need not be at the centre. There may, indeed, be any number of lamps placed anywhere within the sphere. It does not matter what the reflecting power of the surface is, or how the reflecting power may vary from part to part. In particular a portion of the surface may have zero reflecting power, which is equivalent to the removal of that part of the surface, and this portion may be of any shape we please. In all these cases the increase of the illumination due to the reflection is the same for every part of the surface, though, of course, the amount of this increase will depend on the particular circumstances of the case.

Now the brightness B of any part of the surface is related to its illumination I by a simple formula involving ρ the reflecting power of the portion of the surface considered. The formula is

$$\pi B = \rho I,$$

each of these expressions representing the total light sent out by the surface per unit area. If we denote by the suffix zero the values of the corresponding quantities, assuming no increase due to internal reflection, we have also

$$\pi B = \rho I_0.$$

Now by the above theorem we know that for a sphere I exceeds I_0 by the same amount for every part of the surface. It is well known that for a complete enclosure (of *any* shape) whose walls have a reflecting power, ρ, the average illumination I is related to the average initial illumination I_0 due to the direct rays of the light sources, by the formula

$$I = \frac{I_0}{1-\rho}, \text{ or } I = I_0 + \rho I,$$

so that the constant increase of illumination is ρ times the mean illumination. A similar formula applies to B. Now, if ρ is only 10 per cent., B is essentially the same as B_0, and varies to the same extent; but if ρ is 90 per cent., B is on the whole 10 times as large as B, and consists of a small portion B_0, which varies from one part of the surface to another, together with a portion, about nine times as large, which is constant. With the surfaces actually used in an Ulbricht globe the value of ρ is probably about 80 per cent., which means that the constant portion of B is 80 per cent. of the average value of B, the rest is B_0, due to the direct action of the lamp's rays, and varies with the candle-power in the corresponding direction. With such a high value of ρ the error of the measurement yielded by the globe is probably not serious. But there would be a great error if ρ were small and the photometer window partially transparent.

Since the Ulbricht globe is not perfect, I have considered the simpler case of a rectangular box surrounding the lamp and lined with a good white reflecting surface, such as white paper or white enamelled iron. Investigation shows that there is not any simple accurate formula connecting I with I in the case of a rectangular box, as there is in the case of a sphere. But if the reflecting power of the surface is high the brightness will tend to become uniform all over the surface, and I find that *whatever the shape* of the surface is we can assume as a *first* approximation that the brightness of the surface is constant; we have as a *second* approximation

$$I = I_0 + \rho I_m \text{ and } B = B_0 + \rho B_m,$$

or for *every portion* of the surface I exceeds I_0 by a constant amount equal to ρ times the average illumination, the same as for a sphere. This second approximation must be very close indeed to the truth in the case of a nearly cubical enclosure with highly reflecting surfaces.

Now suppose the light to be tested is placed at the centre of a cubical wooden box whose inner surfaces are white and have a reflecting power of about 80 per cent. Let the length of each side be 1 yd., and let the box rest on some horizontal surface. Suppose on one of the vertical sides a hole is cut of dimensions 2 in. by 1 in., and that into this hole is fitted one end of a rectangular wooden tube 8 in. long, the other end being closed by one of a pair of blocks constituting a Joly photometer. The tube is assumed to be horizontal and to be at right angles to the surface of the box. For the present we assume that the tube is open at the end fitted to the box, and not closed by a glass window, as in the case of the Ulbricht globe. The illumination falling on the inner Joly block can be balanced by that due to a comparison lamp of K candle-power placed at a distance D feet from the outer block along the line of the tube.

To calibrate the apparatus it will be necessary to put a light of known mean spherical candle-power within the cube, as in the case of the Ulbricht globe. The mean candle-power of any light used with the cube will then be inversely proportional to the square of the balancing distance D. The only assumption made is that the brightness of the patch of surface used by the photometer is always proportional to the mean candle-power of the light within the cube. As already stated, this assumption is accurate enough provided the reflecting power ρ is sufficiently high. There still remains the question of the best position for the photometer tube. It should be so placed that it does not point to any part of the arc lamp. This is easily arranged, because the area of the patch of surface used is small, less than half a square foot in a side having an area of 9 sq. ft. The part of the surface chosen should not be that where the rays from the arc are strongest, or where they are weakest. We have

$$B = B_0 + B_m,$$

where B is always small compared with the total. All we want for *perfect* accuracy is to have the value of B_0/B_m the same for the patch of surface chosen, whether we test a light of uneven candle-power, like an arc lamp, or calibrate the sphere by a light of fairly uniform candle-power, such as a Fleming standard glow lamp. This end is essentially secured if we choose a portion of the surface the direct illumination of which due to an arc lamp is about the average value due to that lamp. For arc-lamp testing the photometer tube is probably best placed on the middle horizontal line of one of the vertical faces of the box and a few inches in from one of the vertical edges.

There is an entirely different way of using a rectangular box for the present purpose. The theory of this method depends simply on the principle of symmetry. There are few, if any, commercial forms of lamp the light from which is not distributed symmetrically about an axis. Suppose the rectangular box is resting with two of its surfaces horizontal, and that the light is placed at the centre of the box with its axis vertical. It is then obvious that there are four vertical planes through the axis, each of which divides the surface of the box into two halves, and that on each of these halves the total light received is the same. If ABCD is a horizontal section of the box (*see* Fig.), and O represents the axis, the four planes in question are represented by the two diagonals and by the two central planes parallel to the sides. The light received by the portion of the surface consisting of the vertical strip AP, and the two horizontal triangles AOP, will always be a fixed fraction of the total light emitted by the lamp, and in the case of a box of square section this fraction will be $1/8\ (1-\rho)$, or 5/8 if ρ is 80 per cent. Now suppose the box is formed of wood, and that its internal surfaces are well whitewashed. Suppose the part of the box represented by AOP is cut out, and that in its place is fixed a framework supporting three surfaces replacing the missing portions of the box. Let these surfaces consist of a substance transmitting and diffusing light such as opal glass or engineers' tracing cloth. The light received by these new surfaces will still be a fixed fraction of the total light emitted by the lamp, and this will also be true of the amount of light diffused outwards. All that remains to do is to arrange some suitable way of illuminating a photometer by this outwardly diffused light. This object can be attained by the use of two good mirrors, one touching the top and the other the bottom of the box along an edge parallel to SO. Each mirror should be inclined 45 deg. to the surface of the box so as to reflect the light from each triangular area AOP along the line OP. The photometer should be placed along the line OP produced, and from its position the appearance will be that of three flat bright surfaces each perpendicular to the line of the photometer. If the box is a yard cube the size of these surfaces will be considerable, and the photometer distances will have to be large for accuracy. This will be no novelty in arc-lamp testing, since the intensity of the light necessitates large photometer distances. For glow-lamp testing the dimensions of the cube can be made much smaller, as well as those of the rest of the apparatus.

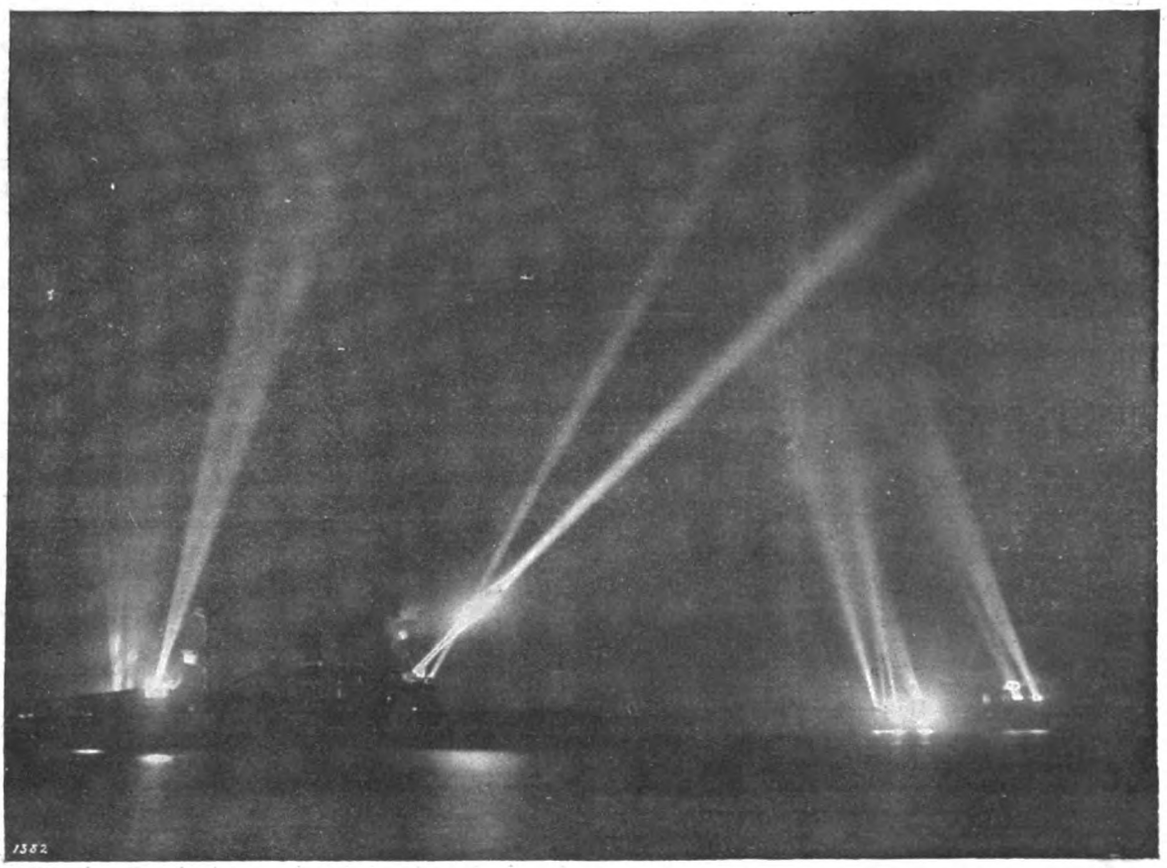
USE OF THE SEARCHLIGHT IN LIFE SAVING.

To the ordinary person the searchlight is often looked upon as an accessory for the killing of people—that is to say, it is used on battleships to help the gun firing and on our coast defences for very similar purposes. That it can, however, be successfully employed for life saving is shown by an incident which occurred at South Shields the other day.

In 1907 our contemporary the "South Shields Daily Gazette and Shipping Telegraph" presented to the South Shields Volunteer Life Brigade a searchlight for use in connection with its work. This brigade was founded in 1866 and has its headquarters at the pier. The projector equipment is placed in the watch house on the South Pier, the generator being in the basement and the projector on the first floor. This floor is fitted with windows all round, so that the projector can be wheeled to any position and throw its light in any required direction. The set operating the light consists of a vertical petroleum engine of Messrs. Norris & Henty's make, delivering 10 H.P. when running at 800 revs. per min. This is coupled to a 65-volt 85-ampere Crompton dynamo, which feeds through the usual switchboard and controlling apparatus a 24 in. Crompton projector.

The formal opening ceremony of this set took place on October 24, 1907, and the volunteer brigade have practiced with it in conjunction with the rocket apparatus every Friday night since. It had not, however, been employed for actual life saving until a week or two ago, when it was used in connection with the rescue of the crew from the Norwegian barquentine "Alphonse." In the course of a storm this ship was driven on the beach 200 yards north of the Trow Rocks, South Shields. Although the rocket apparatus was despatched, the crew did not seem capable of using it, so that after several attempts the lifeboat was launched, and all hands were successfully brought off in it. In connection with the rescue work the searchlight proved itself of great value both to the rescued and the rescuers. From every part of the beach the vessel could be seen as easily as in daylight, although it was nearly a mile distant from the pier. It is, therefore, not surprising to hear that testimonials to the usefulness of the equipment were paid both by the lifeboat brigade and the captain of the wrecked vessel.



CROMPTON SEARCHLIGHTS IN USE DURING THE FLEET ILLUMINATION AT SOUTHEND-ON-SEA.

Messrs. Crompton's searchlights are also being employed for warlike purposes, though the accompanying illustration shows these sometime warriors assisting in the illumination of Southend-on-Sea.

RECENT DEVELOPMENTS IN THE MEASUREMENT OF LIGHT AND ILLUMINATION.

We give below an account of the resumed discussion on the above subject, which took place at the meeting of the Illuminating Engineering Society on Thursday, March 14th, at the Royal Society of Arts.

Prof. SILVANUS P. THOMPSON (president) said that it was intended to confine the discussion on that evening almost entirely to the measurement of illumination and to the carrying out of the principles which had been discussed a month ago in the practical estimation of illumination. It had been hoped that Sir William Preece would have been present to open the discussion, but owing to ill-health it was not possible for him to attend. Happily, however, he was represented more or less by Mr. Trotter, who was associated with Sir William from the beginning.

Mr. A. P. TROTTER said that the subject chosen for that meeting was the photometry of illumination. Query No. 6 of the Paper, which had been circulated, was as follows: "What are the main qualifications of an illumination photometer for practical work? With what degree of accuracy can the illumination in streets and buildings be measured, and what limits of accuracy should at present be permissible?" A member had suggested at the last meeting that there appeared to be too many different kinds of photometers, and he seemed inclined to wait until the best one had been decided upon. There were many kinds of pens and many French dictionaries, but nobody put off learning to write or to study French for such reasons. The fact was that the large variety afforded opportunity for different persons to suit themselves. It would be found that there was no "best" photometer, but each person would generally do the best work with the instrument to which he was accustomed, and, if he happened to be the inventor of one, there could be no possible doubt which instrument he would prefer. He considered that the first of the qualifications of an illumination photometer, which, in fact, distinguished it from a portable candle-power photometer, was the provision of a horizontal test plate having no obstruction, but a clear view all round. Illumination might be measured by measuring successively the candle-power of each lamp which contributed to the illu-

Digitized by Google

mination and then calculating the combined effect. Such measurements might be made on inclined test plates, but the total could only be considered on a horizontal plane. Most illumination photometers could be used also as candle-power photometers. Some instruments, such as the Martens, Kruss and one of Weber's were intended for measuring the illumination on school desks, or at a lathe or bench in a workshop, and the instrument itself obstructed half the view from the test plate, and, in cases of general illumination, might obstruct half of the light. Such instruments were very useful for certain purposes, but were not suitable for measuring illumination in streets, railway stations, &c. The second qualification of an illumination photometer was that the test plate should be as matt as possible—that is, have no appreciable glaze—and should obey the law of cosines as closely as possible—that is, it should have no appreciable angle errors. The third qualification was a good lamp. In Germany a small benzine lamp was often used. The height of the flame had to be adjusted carefully. It could not be used until it had burned for 10 minutes, and he did not know how long it would burn without adjustment. He preferred a small electric lamp worked from an accumulator. If it were switched on only during each reading, which did not take more than 20 seconds, the total over a long evening's work would not amount to more than about half an hour. It was easy to ensure that the lamp would not vary more than 2 per cent. in candle-power during an evening. He did not believe in using voltmeters or adjustable resistances. The fourth qualification was a practical range. The maximum need not be more than 4 foot-candles, but the minimum should reach 0·02 or lower. The minimum illumination for street lighting was sometimes specified as 0·1 foot-candle. It might be interesting to measure the higher values, but in case the lighting was deficient the most important one to be able to measure accurately was the minimum allowed. It was quite possible to make very fair measurements of 0·005 foot-candle, but the scale of the instrument must be expanded at the lower part to make this possible. The fifth qualification was capability for dealing with coloured lights. The speaker's personal opinion was that the value of the flicker photometer was over-rated, but he admitted that good work was done with it in some cases. He considered that the principle of free and rapid motion of the adjustment, whatever it was, of the instrument was sufficient for all practical purposes. The sixth qualification was a convenient arrangement for measuring the angle of incidence, and the last was the important one of portability. The second part of the query related to the degree of accuracy. Any good instrument set up on a tripod should be able to give an accuracy of 2 per cent. But it was useless to attempt high accuracy in outdoor work. Irregularities in glass globes, dirt, variation of gas or electric pressure and other accidental causes introduced unknown errors. If on repeating a number of measurements it was found that they lay within a range of 5 or 6 per cent.—that is, not more than 2½ to 3 per cent. from the mean of the whole—the work might be considered satisfactory. Mr. Trotter then showed one of his illumination photometers, made by Messrs. Everett, Edgcumbe & Co., and explained its use.

Mr. Lancelot Wild (Westminster Electrical Testing Laboratories) said that there were many ways of measuring the insensitiveness of photometers. His way was to move the carriage from the left until one ceased to see any out-of-balance, and then to move the carriage to the right until one again failed to see any out-of-balance, and take the difference between the two. That should be repeated for about a dozen times and the average taken of the different pairs. In that way he had tested a good many photometers, and had taken some of the most notable examples, which were shown in the Table below:—

Insensitiveness of Photometers (Lights of Similar Colour).

Type of photometer.	Equality of brightness. Per cent.	Flicker. Per cent.
Joly prism, paraffin	2·5	—
Simmance wheel	2·4	1·6
Whitman sector	2·0	1·0
Inclined cards	1·2	—
Common Bunsen, viewed one side	1·2	—
Ditto viewed both sides	1·5	—
Special Bunsen, viewed one side (38 lb. Ford)	0·4	0·8
Ditto viewed both sides	0·8	0·2
Special Bunsen, viewed one side (60 lb. Ford)	0·8	—
Ditto viewed on both sides	1·2	0·4
Lummer	0·7	—

The fault of the Joly prism was the separation between the surfaces. With the Whitman sector photometer a great improvement was found by using it as a Flicker. He had come to the conclusion that the reason why the Lummer results were not so good as he managed to get from the Bunsen was because the Lummer was viewed with one eye only, and he showed a photometer of the Lummer type, which was so enlarged that it could be viewed with both eyes without any eye-piece. This proved to be more sensitive than any other photometer that he had ever tried, and had the added advantage that it was comfortable to use.

Mr. J. G. Clarke (Gas Light & Coke Co.) said he could not share the bad opinion that had been expressed of the Bunsen disc photometer. It was part of his duty to keep an eye upon the quality of the mantles belonging to his Company, and for that purpose he found the Bunsen disc a very useful piece of apparatus indeed. In the first place, one could work for very long periods without fatigue, and secondly it would permit an adjustment to be made while one was looking at the screen, which was an important matter. In regard to the testing of lamps, he preferred to test a lamp to ascertain its lower hemispherical value. He mentioned that because a good deal of interest had been displayed in regard to integrating photometers. Of course, it was nice to be able to ascertain such an important value by one observation, but he did not think that one could do with anything less than a complete distribution curve for the light—*i.e.*, to know not only how much light was coming from it, but where it was coming. It was well recognised that a source of light was a sort of raw material for the lighting business, and it was necessary, having obtained an efficient source of light, to consider the best method of distributing it by means of reflection. If one only knew the total flux of light, one was not much better off than if one had no data upon which to base calculations or drawings for the design of reflectors and refracting apparatus. Nothing short of the distribution curve could be of any use. The Simmance-Abady flicker photometer was eminently adapted for the work of getting out such a curve, as it had precise methods of measuring, was easy to manipulate, and with it one could get a distribution curve in about an hour. There were one or two points in regard to the use of the flicker photometer which were rather important. Firstly, there was the speed of the flicker wheel. The speed at which that wheel should run depended upon the illumination which was to be measured, it being necessary that in practical use the flicker should have a lower speed the lower the illumination. In public lighting it was necessary that the various kinds of installations should be maintained at their proper value. In doing that he found it most convenient to conduct the work on the basis of candle-power. Of course, illumination was highly important, and its value should be known at times; but when an installation was once fitted up and the candle-power and height were adjusted to give a desirable illumination, a knowledge of the candle-power which produced that illumination could be taken as an index of the value of that illumination from time to time. For the purpose of taking candle-power measurements he used the Simmance-Abady flicker photometer, which was a very handy instrument for outdoor work that had to be conducted under rough-and-ready conditions, as it was quite firm, and that was a good factor where heavy traffic was encountered. He then demonstrated the use of the above-mentioned photometer, in which he said there was one limitation—viz., that it could only take three sides. That, however, was more or less the case with the Trotter photometer, in which the shadow of the operator was bound to have some effect.

Mr. Haydn T. Harrison said that the query on which they were discussing depended a little upon what one called "practical purposes." For instance, he had had to test over 150 lamps in one evening, each of which were about 80 yds. apart. Simplicity was a great thing, and he thought that Mr. Trotter in his photometer had got simplicity; but he did not agree with Mr. Trotter's remarks concerning the lack of necessity to level the photometer for every reading when using a horizontal screen. He made his photometer so that the angle for nearly all street illumination work varied so little from 90 deg. that the cosine did not have any effect. He found it much quicker when measuring the illumination between two posts to measure the ray at a point where he could measure it accurately; that was where the illumination on the photometer screen was not less than 0·1 candle-foot, and so, as a rule, he raised the height of the photometer and then measured the ray. That was one reason why he objected to the horizontal screen—viz., that the illumination was so low owing to the cosine of the angle. As to permanency of standards, he had been making some tests in that direction, and he found that the small tungsten lamp—preferably tungsten, because the variation of candle-power with pressure was less than in a carbon lamp—remained for over a year within 1 per cent. Another great advantage was that by inserting a resistance the standard of a tungsten lamp could be reduced to one-tenth, and still remained accurate. So that instead of having to put in two lamps in a photometer in order to get a double scale, he put in one lamp and the plug simply introduced the necessary resistance to reduce the standard. He agreed with Mr. Trotter as to accuracy, and never attempted to be more accurate than 5 per cent. for street work. Indoor work, of course, was another matter, and the accuracy obtained depended on how much time one had to spare. Turning to the query as to what were the best methods of studying and measuring daylight illumination, he never attempted to measure daylight illumination in the interior of a building, but always measured the dark spots. He then showed a model of his photometer, manufactured by Elliott Brothers. In all his measurements he used the flicker photometer wherever he could, being thus able to get through much more work in a given time than with a comparison instrument. At the request of the president, Mr. Harrison then measured the illumination of the room in which the meeting was held, the result being, with electric light, 0·7 candle-foot; with gas light, 0·08 candle-foot. In fairness to the gas, however, it should be stated that, owing to it not having been used for some time, probably a number of the burners were out of order.

Mr. P. J. Waldram thought that one important class who neglected the study of illumination was the architect, upon whom great responsibility rested in designing both the daylight and artificial illumination of a building. He considered the human eye capable of absurd fallacies. It would be interesting, he thought, to know what was Mr. Harrison's standard for the adequate illumination of a room.

Mr. K. Edgcumbe said that he agreed with Mr. Trotter that the reflection from houses had a most important effect on the horizontal illumination. For that reason it was not enough merely to take candle-power readings and then to calculate the illumination in a street, as Mr. Harrison did.

Prof. Silvanus P. Thompson thought the Martens photometer, which was extremely simple and portable, was an ideal one for measuring the illumination on a scholar's desk. It certainly stood in its own light, but that was more or less true of every photometer, and, as a matter of fact, the scholar sat in his own light also.

CORRESPONDENCE.

ELECTROMAGNETIC PHYSIOLOGICAL EFFECTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As bearing upon Prof. Silvanus Thompson's interesting discovery of a physiological effect, due to an alternating magnetic field, and as supporting your view that the effect is due to induced currents rather than to any magnetic cause pure and simple, I may mention that it is easy to produce the visual flickering effect by passing through the head the current from an ordinary continuous-current magneto generator, such as is supplied with the Evershed ohm-meter. One terminal of the generator should be held in one hand, while a wire from the other terminal should be held in the other hand in contact with a small piece of wet sponge, and the latter pressed lightly on one side of the head just behind the eye. If the generator handle is then slowly turned (and it is wise to turn it slowly to avoid unpleasant results) the flickering effect will at once become very noticeable, and as the frequency of the flicker increases with the speed of revolution it apparently is connected with pulsations in the current due to the slow revolutions and the few segments on the commutator. The current through the head must be very small, as the bulk of that generated goes from hand to hand through the arms and body.

I first noticed this phenomenon some twelve or fifteen years ago when treating myself electrically for neuralgia, but I fancy that the effects of electric currents on vision have been known much longer than that.

Passing electric currents through the head in certain directions also produces a metallic taste in the mouth.

Electrodeless currents in the body produced by electromagnetic induction from a coil carrying so-called high-frequency currents, have, of course, been in use in medical practice for some years.

Employing as primary a coil of wire of many turns, and some two feet in diameter, carrying high-frequency currents from the discharges of a large battery of Leyden jars, and using as secondary the body and the two arms bent so as to form a circle, sufficient current can be induced in the circuit formed by the arms and body to light a miniature incandescent lamp connected between the two hands; or a sufficient difference of potential can be produced between the two hands to cause small sparks to pass visibly between them when they are held near together.—I am, &c.,

A. A. CAMPBELL SWINTON.

66, Victoria-street, Westminster, April 18.

CONTRACTS IN INDIA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As an electrical engineer resident in the city of Bombay I have noted with interest, on p. 910 of your March 11th issue, that Messrs. Greaves, Cotton & Co., of this city have received contracts for the Cama and Allbless Hospitals, Bombay, and also an order from the Bombay Government amounting to about Rs.100,000. Probably it will be of interest to you to know that the Cama and Allbless Hospitals are also under the Government, and it will be probably very interesting to you and your readers to know that none of these contracts were called for tender. I think this kind of thing would not be tolerated for one moment at home, and I am sure that any self-respecting Government or public body would never dream of handing over large contracts of this sort without at first calling for public tenders.

Of course, I am fully aware that there are many of these contracts for which tenders are called, but it is simply a matter of form, as it is fairly well known beforehand who the particular party is who will receive the order, but still these formulas must be gone through for appearance's sake.

I am also personally aware that there were two or three other contracts given to the same firm, and it seems a most strange thing that the three or four leading electrical engineering firms in Bombay had not even an inkling that this matter was coming forward until the order was given.

I should thank you to give this matter prominence in your paper, and probably some of the powers that be at home might take the matter up and give us all the chance to make a bid. The Government will get much better value for their money if they will call for public tenders, giving the tenderers ample time to go into details, and not, as is the usual practice at present, to call for public tenders for contracts amounting to one to two lacs, which have to be submitted within a day or two.—I am, &c.,

Bombay, April 1. ONE INTERESTED.

[We have somewhat modified our correspondent's letter (of April 1st), as there are statements made therein that we are not able to verify. The subject of public tendering is one that demands publicity and, if the facts are as stated, "One Interested" does good service in calling attention to them.—ED. *E.*]

ELECTRICITY IN MINES.

At a meeting of the Mining Institute of Scotland, held last week in the Technical College, Glasgow, an interesting discussion, of which we give an abstract below, took place in connection with Mr. Robert Nelson's Paper on "Electricity in Mines."

The PRESIDENT, Mr. Robert McLaren (H.M. Inspector of Mines) stated that in Scotland electrical power was now largely utilised, and he, personally, did not see why Scottish mining engineers should not be able to contribute usefully to a discussion of this subject.

Mr. C. A. ATCHLEY thought that the completeness of Mr. Nelson's Paper made for criticism, owing to the fact that so many controversial points were discussed. Mr. Nelson's strong defence of the three-phase system of supply as against continuous current would, no doubt, meet with cordial agreement on the part of most engineers as a general statement. Unfortunately, mining conditions might also have to be taken into consideration, and in these days of extremely thin seams continuous current had perforce to be adopted for coal-cutting, owing to the greater power which could thereby be obtained from a small motor of given size. In any case, judging from the extremely satisfactory results which continuous-current machines had given for this class of work, it would appear doubtful whether a change to three-phase supply would be a great improvement, especially as the nature of the work rendered slip-rings almost a necessity. There did not seem to be a great deal to choose between a commutator and slip-rings, both, in his opinion, being equally objectionable in places coming under Section 8 of the Coal Mines Regulation Act. He felt bound to question Mr. Nelson's advocacy of the concentric system, as in his (Mr. Atchley's) experience it had been a source of trouble, owing to its very construction inviting a breakdown of the insulation, and a proper repair was difficult to carry out satisfactorily. Vulcanised bitumen had undoubtedly proved the most satisfactory insulating medium, and in conjunction with this, armoured cables in all main roads, as suggested by Mr. Nelson, would seem to offer a cable as good as any that could be devised. On the other hand, Mr. Nelson's recommendation as to the use of a copper sheath for earthing purposes, in addition to armouring, might be desirable and necessary in parts of the country where it was the practice to work over very large fields, but in Lanarkshire it would surely appear to be quite unnecessary. Mining engineers would welcome Mr. Nelson's definition of satisfactory earthing, as this had been a contested point almost since the time when the necessity for earthing in connection with mining electrical installations became an acknowledged fact. To those engineers who had become used to the unarmoured cable system and who had adopted the armoured system it would seem necessary to emphasise Mr. Nelson's warning that such a system was much more dangerous than that embodying unarmoured cables unless every precaution was taken to ensure that the whole armoured system of the pit was made electrically continuous to suitable earths. In regard to the new system of protection referred to by Mr. Nelson, since the suitability of this apparatus had yet to be determined, it was, perhaps, too early to comment upon it, but he (Mr. Atchley) could not help expressing the opinion that it did not appear to be so simple as it looked.

Mr. F. ANSLOW (Glasgow) said Mr. Nelson's Paper contained so many useful hints for the design and carrying out of electrical mining equipment that from that point of view it must be of great practical value to those engaged in the equipment or management of mines. When, however, in this and the Paper read recently at Birmingham, Mr. Nelson dealt with the various systems he was scarcely so convincing. In the present transient state of electrical matters it appeared quite an erroneous procedure to advocate that any particular system of supply, source of supply, or class or type of cable should be universally used. As regards the system of supply, being interested in a large amount of alternating-current plant at present being installed, he (Mr. Anslow) was satisfied that that system possessed many valuable features, especially for use in fiery mines, but its application, he thought, was limited. Direct current had also its special points, not the least of which was its more general adaptability for driving any class of machinery, and it appeared

Digitized by Google

to be quite within the region of possibilities that this power would regain its once pre-eminent position. In many cases, indeed, where alternating current was used, converting apparatus had to be installed for supplying direct current to machinery which could not be operated efficiently by alternating current. Regarding the source of supply, no doubt the various power companies had been a boon to collieries in isolated districts; on the other hand, however, it was not clear, in view of many instances which had come under his notice, that power companies could supply electricity at a cheaper rate than that at which it could be generated in even a moderately-sized power station situated at a colliery. It must not be forgotten that in many existing collieries use could be made of exhaust steam, and further, especially in Scotland, there was frequently a quantity of dross available which had no marketable value, and which, having quite a good calorific value, could be economically used for steam-raising purposes. He thought Mr. Nelson was quite right when he stated that the use of armoured cables ensured the work being properly carried out. Such cables were particularly adaptable, of course, to the protective system recommended by Mr. Nelson.

Mr. Sam Mavor (Glasgow) thought that Mr. Nelson's official capacity gave his Paper exceptional authority. The author curtly dismissed continuous current in favour of the three-phase system. Now, the speaker did not think that was warranted. For large areas of supply, and in the case of large collieries requiring to transmit power a considerable distance, there was no question whatever that three-phase was the right system. In Scotland, however, there was a large number of relatively small colleries requiring relatively small quantities of power, and it was not, in his opinion, to be accepted that the three-phase system was necessarily the best for these conditions.

Mr. Anderson supported Mr. Mavor as to direct-current versus three-phase coal cutters. In many cases colliery managers were badly advised to adopt the three-phase system. It had, he noticed, been represented in one of the contributions read that evening that the use of armoured cables tended to better workmanship. His experience in coal mines, however, had been the very opposite. He did not think that he had seen more shoddy work carried out anywhere than where the armoured system was adopted, possibly due in a measure to the fact that those in charge of armoured cables did not realise the great responsibility. He also considered that there should only be one earthing point in connection with a colliery installation, and that earthing point should be on the surface.

The President stated that he was not greatly taken up with armoured cables, because they got twisted in all sorts of ways and the wires got away from the cable.

Mr. Martin remarked that in the Newcastle area he happened to know, from practical experience, that the protective system advocated by Mr. Nelson had proved of real value.

Mr. James T. Forgie (Bothwell) thought that those who had had experience of electricity for a number of years found that in a great many mines in Scotland the continuous-current system had proved remarkably satisfactory. They must remember that Mr. Nelson's experience had been mostly gained in large collieries; and in such places, with long transmissions, the alternating system was certainly the best. The speaker had no hesitation in saying, however, that for a small installation the continuous-current system was the best.

ELECTROLYTIC DISINFECTANTS.

In our issue of November 23, 1906 (p. 205) we described the Hermite plant installed at Poplar for the electrolytic production of hypochlorites; and details of the results obtained with this plant are contained in the annual reports of Dr. Alexander, the medical officer of health, which reports have been abstracted from time to time in our columns.

As mentioned briefly in our last issue, additional plant has recently been installed at Poplar, and on Tuesday last the complete installation was visited by the Faraday Society, the particulars of the process being explained to the members by Dr. Alexander.

The new plant has been installed by the side of the existing plant in a building adjacent to the Poplar electricity works, from which current is obtained for the electrolytic process. The most important feature of the new plant is the new type of trough, or cell. These cells are now made of earthenware. Slate was employed in the old troughs and has not proved satisfactory, owing to the difficulty of obtaining a slate without metallic veins. The presence of these veins causes the slate to be destroyed, and earthenware has been found to give much better results.

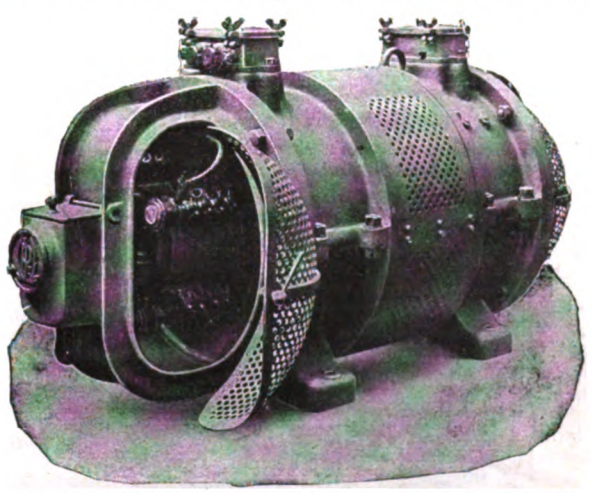
It will be remembered that the system adopted at Poplar is to mix sodium chloride and magnesium chloride in an elevated tank and then to allow this fluid to flow through troughs containing the electrodes. Each trough is divided by a partition, and five elements, each consisting of one positive and two negative electrodes, are placed in each division. There are four troughs, so that the total number of elements in series is 40. The positive electrodes consist of thin platinum wire wound upon slate slabs, and the negative plates are of zinc. The liquid passes through all the troughs and finally discharges into a carboy. The preservative is added as the liquid leaves the last trough, and an electrically-driven stirrer in the carboy is now employed in place of the hand stirring formerly necessary. A pump has also been installed for raising the fluids into the elevated tank. Improved forms of electrode have also been adopted in the new installation, facilitating connecting up.

A current of about 25 amperes at 240 volts is used for each plant, and, of course, a new switchboard panel with resistances has been installed in connection with the new plant. It may be mentioned that the cost of the new plant, which has been supplied by the Farringdon Engineering Co., is about £400, including the new switchboard. The complete installation comprising the two plants has cost about £1,000, and approximately 400 gallons of disinfectant fluid are produced per day, this being the amount of the present requirements. The cost of production is a little more than ¼d. per gallon for electricity and materials. The disinfectant fluid is supplied free to all applicants. We must congratulate Dr. Alexander on the success attending this pioneer installation.

SELF-REGULATING DYNAMO FOR USE WITH SEARCHLIGHTS.

The advantage of using a source of electricity supply giving a current of constant value for the lighting of arc lamps of any description is well known. For searchlight work, where the lamps are used independently of each other, the advantages of such a supply are still more noticeable, and the want of a suitable dynamo for generating a constant current has been the main reason for resorting to less efficient means of operating this type of apparatus.

A dynamo which Messrs. Mather & Platt, of Park Works, Manchester, have designed and put on the market for this class of work, is said completely to solve this difficulty. It generates current at practically constant value throughout a range of voltage far beyond



Constant Current Dynamo of Messrs. Mather & Platt.

the limits required for arc lamp working, and is further free from many of the objections which might be raised on the score of complication. The regulation of the machine is entirely automatic, while this condition is obtained without the use of any external regulating "devices," either mechanical or electrical. The terminals of the machine may be completely short-circuited, or may be closed through a resistance of a value sufficient to maintain a potential of over 100 volts at its terminals with a variation in current of practically negligible amount. The current can, it is claimed, be further increased or diminished within wide limits without in any way affecting the self-regulating properties of the dynamo, merely by an alteration of the existing current. The same generator may, therefore, be used for arc lamps of varying current requirements, thus much increasing its utility, as it is perfectly practicable to run a 15 ampere or a 125 ampere projector off the same size of machine.

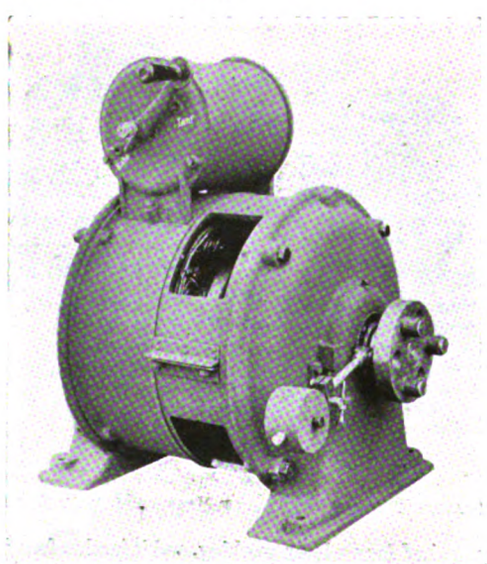
Apart altogether from the chief advantages which this system possesses, in virtue of its high efficiency, it has other recommendations no less interesting. Not only is the dynamo itself simple in construction and operation, but the whole management of the projector is much simplified by its use. The current is switched on by merely closing the circuit of the dynamo; an arc forms immediately and is drawn out to the correct length, either automatically by the solenoid of the projector, or by hand if automatic regulation is not used. There is no sudden rush of current, no flickering of the arc and jumping of the carbons, and the time required to get the full brilliance of the arc

Digitized by Google

is very much shortened. There is no risk of fuses blowing, due to excessive current being taken, and no need to burn the arc a moment longer than is actually necessary, as it can be re-started instantaneously. The saving on this score alone, both in carbons and in energy, is by no means insignificant, as frequently arcs are kept burning solely on account of the difficulty in re-starting them. Owing to the steadiness of the current obviating the slightest tendency of the arc to hunt, the candle-power of the arc is found to be appreciably greater for the same current consumption and voltage across the arc, or, in other words, the same candle-power can be obtained with a lower pressure across the arc. The difficulty often experienced on low-voltage circuits of the arc being extinguished by being drawn out too far, or too quickly, is almost entirely absent, as the dynamo voltage accommodates itself to the conditions of the arc, and it is possible to draw out an arc 25 mm. to 40 mm. long with a current of 50 amperes. The dynamo can be arranged either for direct coupling to a prime mover, belt driving, or for coupling to a motor in cases where a supply of current is available, as shown in the accompanying illustration.

ELECTRIC DRIVE FOR RING SPINNING FRAMES.

The ring frame has brought about great changes in cotton spinning, and the self-acting mule has, in consequence, been more and more restricted to fine spinning. For this class of work the ring frame has not hitherto been seriously considered, since owing to the comparatively low tensile strength of fine yarns, the quality of the production is very seriously affected by the varying tension to which the yarn is subjected in ordinary ring spinning. A special motor with provision for the periodical variation of its speed has now been placed on the market by the Oerlikon Co., by means of which more favourable results can be obtained on fine counts than are possible with a constant speed drive.



OERLIKON MOTOR FOR RING SPINNING FRAMES.

The tension in the thread varies with the different diameters of the cop, and is greatest when the smallest portion of the cop is being formed. This varying tension in the thread is the chief cause of broken ends, and also results in uneven winding. On the self-acting mule the tension in the yarn is readily regulated through the medium of an arrangement of the most ingenious mechanism, whilst on the ring frame a modification of the frictional resistance to the traveller is the only means which can be resorted to in order to regulate the tension in the yarn. This variation of frictional resistance to the traveller can only be obtained by altering the speed of the traveller and the spindle speed with each upward and downward movement of the ring rail. The introduction of a varying spindles peed also affords a means of considerably increasing the output of the machine by gradually increasing the speed at the middle and lower end of the bobbin, the utmost speed being applied according to the diameter spun.

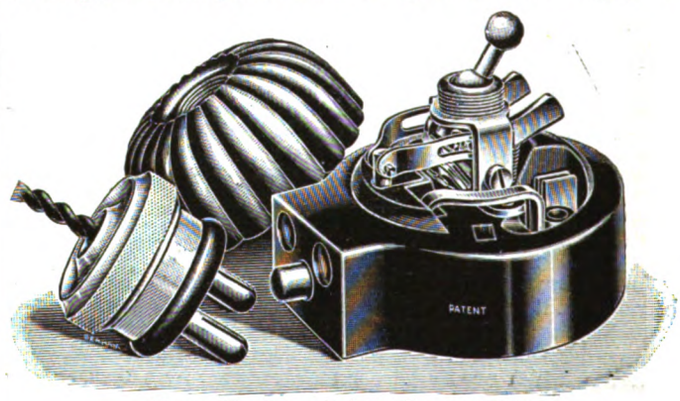
The single-phase repulsion type of motor has furnished the desired solution of the problem, for by means of a simple device for changing the position of the brushes a regulation of speed without shock has been obtained with very little change in the efficiency of the motor. The Oerlikon ring-frame motor (illustrated herewith) possesses a speed variation from 600 to 1,430 revs. per min., and may be adjusted to any speed between those limits whilst work is in progress. The Oerlikon motor possesses the advantage of having only one set of brushes for each pair of poles, thereby simplifying the construction, and it is claimed to have an electrical efficiency little inferior to that of the three-phase induction motor. It may also be mentioned that the motor is dust-tight, and is provided with ball bearings. The starter is fixed on the top of the motor, the lever handle moving between two fixed stops.

As to the automatic apparatus for the periodical variation of the spindle speed corresponding with the mechanical formation of the cop, the Oerlikon arrangement consists essentially of a rope fixed at one end, and the other end connected with the lever noticed in the illustration herewith; this lever is provided with a weight to hold the rope in its normal horizontal position, and connects its movement with that of the brushes on the motor. Attached to the centre of this rope is a second rope which receives a downward pull actuated from the mechanism.

To show the economies which may be effected by the application of the Oerlikon electric drive, some tests on a Rieter ring frame at the Niedertöss spinning mill may be cited. Three frames of the same manufacture were compared, two of these being belt-driven, and the third fitted with the variable speed Oerlikon drive. The actual production over 52 working hours was 122 lb., 133 lb., and 162 lb., respectively, for the three machines. Besides the increase in production, it was observed that a lighter traveller could be used on coarse and medium counts with the variable speed drive.

LUNDBERG'S "AUTO-COMBINATION,"

Messrs. A. P. Lundberg & Sons' ingenuity has, if they will allow us the phrase, broken out in another place. The increasing use of electric heating and cooking apparatus, taking a fairly large current, requires that some efficient means should be taken to protect the equipment, while at the same time any design adopted must be simple enough to allow the ordinary householder to operate it with safety. These conditions are, it is claimed, fulfilled by the 10 ampere capacity auto-combination, a specimen of which has been sent for our inspection. A smaller size, having a capacity of 5 amperes, is in preparation. This piece of apparatus is a combined switch and wall connection, fitted with an automatic release, the latter device being covered by a recent patent taken out by Messrs. Lundberg. The



MESSRS. LUNDBERG'S AUTO-COMBINATION.

switch movement is of Messrs. Lundberg's well-known standard patent pivot type, with the valuable double action, and is of essentially up-to-date construction, that is, it is fitted with knife-blade contact arms and double contacts, while the mica insulation has been successfully tested to withstand a 2,000-volt flashing test before breaking down. By the provision of a spring embodied in the base, which is in connection with the rocking cradle of the switch arm, a device has been arranged to ensure automatic release of the switch contact arm before the plug can be withdrawn. Messrs. Lundberg claim the following advantages from the use of such a device :—

The contact arm flies automatically into its "off" position before the plug can be withdrawn, and remains there. The rupture of the circuit on the withdrawal of the plug is rapid and independent of the operator, the break occurring at its proper place—viz., at the switch contacts. While the plug is in position the device does not prevent actuation of the switch in the usual way. The withdrawal of the plug is thus only necessary when the apparatus connected requires removal. The plug must first be pushed into full contact before the switch arm can be made to remain permanently in its "on" position. As the circuit cannot be broken where the plug pins leave the socket tubes any destructive arcing at these points is effectually prevented. The article can be fitted with any of the standard plugs, and is suitable for ordinary or locked-type covers.

PARLIAMENTARY INTELLIGENCE.

BRADFORD CORPORATION BILL.

The Local Legislative Committee of the House of Commons (presided over by Mr. C. N. Nicholson) has continued the consideration of this Bill, by which means powers are sought to construct tramways and to run rail-less trolley omnibuses, &c., in Bradford.

Mr. C. J. SPENCER, general manager of Bradford tramways, was recalled and stated that if the trackless tramways proved unsuccessful, the Corporation would not desire to continue them. They were convinced that the scheme could be worked at the fares indicated, without loss. There was no suggestion of going below the 1d. per mile in the first experiments. Owing to the enormous cost of electrical traction they must have a route which would stand a very frequent service of trams. On the Laisterdyke route there was no such demand as would justify a constant service. It would be possible to work the trackless trolley system on even crowded routes by a driver only. What they wanted to have power to do, was, subject to the clause that had been agreed with the railway companies, to carry goods and minerals on the trackless system within Bradford, and, with regard to motor vans and omnibuses, to carry parcels up to 56 lb., as they were doing now.

Col. YORKE, of the Board of Trade, called by the Committee, said the Board had nothing to do with omnibuses, whether mechanically propelled or horse-drawn. They did not come under the Board of Trade except in the case of Eastbourne, where certain special clauses were put in the Act of 1902. In regard to the proposed trackless trolleys, the original proposal in the Bill was that there should be no restrictions on the Corporation at all, but that they should be given a general power and be allowed to settle their routes as they chose. And in consultation with the Board, an arrangement was come to by which they were to be consulted before any fresh route was adopted. It might be that if a trackless trolley system were authorised on a certain route, the Corporation owning it might propose hereafter to lay down rails on the route; they might consider that they would have a sort of right, and it was possible that that route might not be suitable for a tramway, although suitable as an experiment for the trackless trolley. That was one of the points they had in mind. He thought it would be a sufficient safeguard, in the interests of the general public, that an inquiry should be held by the Board of Trade, instead of the Corporation being bound to come up for power for a fresh route.

Mr. HELME, M.P.: If we gave powers, subject to a local inquiry by the Board of Trade, to be confirmed by a provisional order, that would give the right to the public on the one hand, or to the Corporation on the other, to come to Parliament, and if necessary oppose the provisional order, that would relieve the Corporation in future from the greater expense of prosecuting the Bill?—Yes, that may be a way to meet it.

Replying to the Chairman, Mr. JEEVES (for the Corporation) submitted that the necessity of coming to Parliament would not exist in the case of the trackless system, and he was understood to say that he thought they would be prepared to continue the trackless tramway, taking the risk whether they got permission to convert into a tramway later on. He pointed out that there was an intermediate course. It would be possible to provide that an order should be made by the Board of Trade, and to come into operation unless within a specified time objection were taken, in which case it should, ipso facto, become a provisional order, and be subject to provisional order procedure. It would make an appeal to Parliament possible, but not obligatory.

Mr. A. R. FEARNLEY, general manager of Sheffield Corporation tramways, gave evidence in favour of rail-less traction, and said it was intended in their next Bill to come to Parliament for powers. He had recommended the system to the Corporation. He hesitated to say it would be suitable for carrying heavy goods, but he certainly endorsed it for light goods.

Mr. J. M. MCELROY, general manager of Manchester Corporation tramways, regarded the system as a cheap and ready mode of transit which, if powers were granted, could be operated without loss.

Mr. J. B. HAMILTON, general manager of Leeds Corporation tramways, said there had been found in that city the same sort of agitation in outlying places for electric traction in some form, which they had not been able to comply with because of the cost. He was satisfied the rail-less trolley system could be worked at the cost of an ordinary tramway. If the powers asked for were granted, they would be enabled to have this kind of traction in districts where it was altogether impracticable to have it to-day. He had been delighted with the practicability of the scheme, and he was in general agreement with all that had been said by Mr. Spencer.

On Tuesday, Mr. C. J. Spencer submitted a statement dealing with the operations of the parcels department on the tramways. The average amount received per parcel was 3·36d. For the past year there was a net profit of £1,028 on the carrying of parcels, or about 14 per cent. on the turnover. They carried 600,000 parcels, and £50 was included in the balance-sheet for parcels carried over the tramways. The point of view of the Tramways committee was, "What does it cost the tramways department extra to carry these parcels?" That was not quite the same thing as if the committee were dealing with an outside firm who wanted a concession. It was agreed that £50 was an outside figure, but if it were ten times the amount it would not wipe out the profit. £169 was included in the balance-sheet to cover wear and tear of the car by reason of the parcels being put on in addition to the ordinary user. With regard to the allegation that the Corporation carried parcels outside the city boundaries, Mr. Spencer said he found some two years ago that the Corporation did run some goods to Huddersfield, but their practice at present was for goods to districts outside their area to be handed over to the local carriers and to other tramway systems. At least 95 per cent. of the parcels carried went by tram.

Further evidence in opposition to the tramway clauses by the carriers and cab proprietors was then taken, and Mr. Pollock addressed the Committee in support.

Mr. JEEVES, on behalf of the Corporation, said the bill as first submitted provided for powers to deal with trackless trolley and other vehicles in one clause. It was pointed out that such a clause would enable the Corporation not merely to run these trackless trolley vehicles, but also to run self-contained motor vehicles to any part of the city. That was not really the desire of the promoters, and he at once undertook that the clause should be so amended as to make it perfectly clear that the special powers asked for should be limited to trackless trolleys only. All that was now asked was that they should have power to run these vehicles on such routes as the Board of Trade might determine, and then they would merely become part of the tramway system, feeding the main routes from thinly populated districts which could not afford to maintain a more permanent form of track. It was said there was no precedent for this power. It was true no precedent had been carried out, but at Stroud powers were granted to construct trackless trams to a company, a company which found itself unable to raise the money. In that case the routes were defined, but since then the question had been raised before a Parliamentary Committee on the Leeds Corporation Bill, and there the desirability of the principle had been admitted. With regard to motor-omnibuses, in some of the earlier cases routes were prescribed, but in the later cases power had been granted to run these vehicles within a defined area, so that there was nothing so revolutionary in applying the principle to the trackless trams. The power to carry parcels and goods on tramways and trackless trolleys, while new to Bradford, was not new as regarded tramway undertakings as a whole. The powers were merely those which Manchester Corporation had, and Bradford did not ask for any powers which would interfere with what was known as the Manchester judgment.

At the close of the speeches the Chairman intimated that the Committee would reserve their decision on the tramway clauses, as it was a matter of very considerable importance, and especially considering that the point was raised by another bill before the other House.

On Wednesday Mr. NICHOLSON, in giving the committee's decision, said the Committee approved of the principle of the trackless trolley system for experimental purposes on the route described as tramway No. 1. Its extension to other routes should be sanctioned only under the powers of either a private bill or of a provisional order, and the same procedure would apply to any possible conversion from the trackless trolley system to an ordinary tramway. The Committee suggested that the accounts of the trackless trolley system should be kept separate from those of the general tramway undertaking of the Corporation, so that, if future similar applications were made, the Committee could have the financial results of the experiment in Bradford put before them.

RHONDDA URBAN DISTRICT COUNCIL (TRAMWAYS EXTENSIONS, &c.) BILL.

On Tuesday the Local Legislation Committee of the House of Commons, presided over by Sir F. Layland Barrett, considered this bill.

Mr. FREEMAN, K.C., for the promoters, said the Council's tramways were at present leased to and worked by the Rhondda Tramways Co. The lease was for 42 years. A small portion of the system was opened in July, 1908, and the remainder on Nov. 9, 1908. In 1909 8,821,000 passengers were carried, and the gross profit was £22,419. In the present year the results, so far, were even better. It was now proposed to take powers for the construction of three extensions (about 3 miles in all) from Treherbert to Tynewydd, from Ferndale to Maerdy, and from Pen-y-Graig to Williamstown. Under the Council's 1902 bill they would take over the present system at the expiration of the lease at an amount equal to the accumulated annual rent paid, with compound interest at 3½ per cent., but the company would only carry out the extensions now proposed on condition that they were ultimately taken over at their market value as a going concern, and the Council were prepared to agree to that. The estimated cost of the extensions was £35,000. The Taff Vale Co. opposed on the ground of competition, and also as ratepayers on the ground that the lines might not pay, and the South Wales & Monmouthshire Coal Traders' Association opposed on the ground that there was not sufficient protection for the ratepayers. The only portion which would compete with the Railway Co. was that between Treherbert and Tynewydd, but that was sanctioned in the Council's 1902 bill, and it was now proposed that the power with regard to that should be revived. The tramways were rated at about £2,000 a year, and they would have been more beneficial to the district if, owing to opposition to their former bills, they had not been precluded from constructing the tramways themselves. The present population of the district served by the tramways was 138,700.

Mr. ROBT. HAMMOND gave evidence in support of the Bill, and said the estimate of cost of construction appeared reasonable. The company had not allowed for depreciation during the past year, but it was probable that the increase of traffic would in future cover depreciation, and also permit of the payment of rent and dividends.

On Wednesday Mr. LLOYD, K.C. (for the Taff Vale Railway Co.), said it was now proposed that the Council should have the right to acquire the projected extensions at a superimposed cost, although they were already included in the original arrangement that the Council should

Digitized by Google

acquire the whole undertaking for £258,000, less 25 per cent. for depreciation. At a Board of Trade inquiry held before the passing of the Council's 1902 Bill, Mr. Pollock, on behalf of the Board of Trade, said the Council could not calculate upon funding the rent received at a higher rate than 3¼ per cent., which would produce £196,000 to cover the £193,875, the value after deducting 25 per cent. Mr. Lloyd went on to say that the 1902 Act intended that the capital should not exceed £258,000, as otherwise the funded rent and interest would not be sufficient to wipe off the capital minus 25 per cent., and that the Council should have the option of buying at tramway price, under sec. 43 of the Tramways Act, and that such price should not exceed the funded rental. There was no case shown for departing from that principle. The company had made 6 per cent. in their first year because of the novelty traffic and the absence of provision for depreciation, but it would be different when they had to face renewals. Much traffic had gone from the Taff Vale Co. to the tramways. He still objected firstly to the construction of the extensions, and secondly to the superimposed bargain with regard to the extensions.

Mr. O. Beasley, general manager of the Taff Vale Railway Co., said his company had spent nearly a million on accommodating the traffic in the Rhondda Valleys. The tramways had carried nearly nine million people, and they had seriously crippled the Taff Vale Railway's passenger traffic. The railway paid 4 per cent., but if the original capital and original shareholders existed it would be 10 per cent.

The Chairman announced that the Committee had unanimously come to the decision to give the powers to make the tramways and to assent to the terms of the agreement between the Council and the Company.

LEGAL INTELLIGENCE.

B. Spencer v. London United Tramways (Ltd.)

In the Divisional Court on Saturday Mr. Justice Phillimore and Mr. Justice Bucknill heard an appeal against judgment and verdict in this action brought by plaintiff for damages for personal injury. At Brentford County Court the jury returned a verdict for plaintiff for £15. Against this the Tramway Co. appealed, on the ground of misdirection and that the verdict was against the weight of evidence.

Mr. Glasgow (for the company) said the complaint of appellant was that the judge was wrong in law in holding that there was evidence of negligence on the part of defendants' servants, and should not have allowed the case to go to the jury. The circumstances disclosed were that while plaintiff was in the act of boarding one of defendants tramcars the car increased its speed and defendant was thrown into the road and injured. At the second trial evidence was given that plaintiff was standing at some little distance from the " stop if required " post, and when the car was a short distance off he, by raising his hand, signalled the driver to stop. The driver slowed down as he was approaching the stopping post, and plaintiff grasped the stanchion bar in the middle of the platform, but the car at that moment increased its speed, and the man was pulled to the ground and dragged about 40 yds. There was no evidence that the driver saw the signal to stop beyond supposition, and he asserted that he did not ; that he slowed down in case anyone should desire to get on or off the car at the " stop if required " post.

Mr. Justice Phillimore said that if the driver slowed down on approaching the stopping post it was an invitation for people to get on, and if he suddenly increased the speed without stopping it would be negligence.

Mr. Justice Bucknill said that if there was evidence that the driver saw the signal the direction of the judge in the Court below was right.

Mr. Justice Phillimore said the practice was for people, as the car slowed down on approaching a stopping point, to get on board. There was a bye-law which said that passengers were not to enter the car while in motion, and the judge had to say whether the passenger's negligence was the cause of the accident, or whether there was something which defendants must do to counteract such negligence. If the driver knew that it was the practice for people to board the car while in motion was he not negligent if, when he saw someone coming, he did not see that the person was on board before he increased the speed again ? Whether he saw the passenger or not, if he had once slowed down in that way, he took the risk if he increased the speed before he reached the stopping place, without being sure that no one was getting on or off. If he did not take that precaution was he not guilty of negligence ?

Mr. Glasgow submitted that he was not. The driver invited the man to get on only when he had stopped the car. In this case he had simply slowed down in case it was necessary to stop. He did not see the man, and unless he did see him he had a perfect right to do what he had done.

Mr. Justice Phillimore, without calling upon the other side, said there was nothing in the judge's summing up of which the applicants could complain. The jury were directed that they could only find for plaintiff if they believed the driver saw him, and that was quite right. If a driver knew that a man was approaching to board a car as it was approaching a stopping place, and begins to slow down the man knew that the driver was responding to his signal, and took the slowing down as an invitation to board. And although it might be that the man was negligent in trying to board before the car stopped the driver was negligent in not completing the process of stopping, and in going on at a faster pace without being convinced either that the passenger was on board or had given up his intention of boarding the car. The jury had been properly directed, and there only remained the question as to the evidence upon which they could find that the driver saw plaintiff. On that the evidence was certainly very slight, but it was enough for the jury, and the appea must be dismissed.

Mr. Justice Bucknill concurred.

The appeal was dismissed, with costs.

Electrical Co. (Ltd.) v. Thomas, Son & Co.

This action was continued before the Official Referee (Mr. Pollock) this week.

Mr. Wales was called for the defence and said that a month would have been a fair and reasonable time to unwater the mine after the installation of the plant. He estimated the amount to which defendants were entitled, in respect of damages, at £27,900.

Rebutting evidence was called by plaintiffs, and Mr. F. B. Johnson, electrical engineer, said he erected the plant for plaintiffs in defendants' mine. The machinery, he declared, was allowed to get into such a dirty condition by defendants' men that it would not work properly, and the generating plant would not produce the required amount of current. The sump of the Allen pump was allowed to get into a very bad state, and the water was very dirty and thick with clots of grass floating in it. Witness mentioned occasions when the pump was not allowed to work in a sufficient depth of water, with the result that it drew air, and it would have to be stopped. If it were allowed to run on it would heat up the pump machinery and bearings.

G.E. Railway Co. v. Leyton Urban Council.

On Tuesday Mr. Justice Phillimore heard a special case stated by the arbitrator in the matter of the G.E. Railway Co. and Leyton Urban Council. The question at issue was whether, on the conversion of tramways from horse to mechanical traction, involving an increase in the weight of the tramcars, the owners of the cars became responsible for any payment in respect of the further repair and strengthening of the structure of bridges over railways rendered necessary by the additional weight and vibration they had to bear in consequence of the increased weight and speed of the tramcars. The particular question was in regard to the Lea Bridge, which the G.E. Co. had been compelled to strengthen and partly to reconstruct on account, as they alleged, of the conversion of Leyton Council's trams from horse to electric traction.

Mr. Eldon Bankes, K.C., for the G.E. Railway Co., argued that under sec. 55 of the Urban Council's Act of 1904 provision was made for remuneration to the company by the Council if the conversion of the trams to electric or any other mechanical traction led to increased vibration and strain on the structure of the bridge.

Mr. C. A. Russell, K.C., for the Council, contended that the facts disclosed did not bring the case within the section cited.

Mr. Justice Phillimore said the section might have been more clearly expressed, but he was of opinion that the construction contended for by the railway company was right. The reconstruction of the bridge was rendered necessary by the increased weight of mechanically-driven cars. It was possible to provide cars of no greater weight than the horse cars, but that would not have been an economical practice, nor in accordance with the custom of this country, which was that mechanically-driven cars, particularly in a district like Leyton, where there was a great number of passengers, should be heavier and give greater accommodation than would be possible with the lighter cars. He therefore gave judgment for the railway company, with costs.

Assessment Appeal.

At the Liverpool County Sessions on Tuesday the Liverpool District Lighting Co. appealed against their assessment in three different townships by the Assessment committee of the West Derby Union.

Mr. Rigby Swift (for respondents) said the appeals were in respect of the company's generating station at Waterloo, whose mains ran through the townships of Waterloo, Crosby and Seaforth, and of " free " wiring in the houses of electricity consumers. At present the whole undertaking was rated at £740 net, and if the contention of appellants was right that the expenditure of £7,510 in respect of the installation of " free " wiring must be regarded as tenants' capital, it had been agreed that the amount must be reduced to £350 net.

Mr. F. A. Greer (for appellants) argued that the outlay on " free " wiring was that of a tenant undertaken for increasing his business, and ought not to be taken into account in estimating the ratable value of hereditament.

Sir William Forwood said that in the opinion of the court some deduction ought to have been allowed in the valuation in respect of the tenants' capital employed in wiring the houses. Having come to that conclusion, they were bound by the agreement that had been made to fix the ratable value at £350. They, therefore, allowed the appeals, with costs. He must, however, say that the figure was not one which the court would have fixed had it been left to them.

On the application of Mr. Swift the bench agreed to state a case for the Higher Court.

J. E. Cutler v. London United Tramways (Ltd.)

On Tuesday, before Mr. Justice Scrutton, plaintiff was awarded £350 damages for personal injuries received whilst riding on the top of one of defendants' cars. Plaintiff said that the car jerked so violently whilst running from the main track on to a loop line at Southall that he was thrown from his seat, and his head striking the seat opposite so seriously injured his left eye that he had to have it removed.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

An inspector of telephones is required by the Government of Ceylon for an engagement of three years. Salary £200, and an allowance of R.6 per day to cover cost of subsistence when away from headquarters. Applications to Messrs. Preece & Cardew, 8, Queen Anne's-gate, London, S.W., by 30th inst. See an advertisement.

A leading draughtsman is required by a first-class electrical firm, to take charge of drawing office; must be used to h. and l.-t. switchgear. See advertisement.

A draughtsman is wanted for switchgear design, both h. and l.-t. See advertisement.

There is a vacancy for a premium pupil at Watford electricity works. Applications to the Chief Engineer. See an advertisement.

A man is required to take charge of suction gas electric plant, accumulators, &c., on an estate in Herts. Applications to Estate Offices, Erpingham, Norwich. See advertisement.

The Committee of Visitors of the Essex and Colchester Lunatic Asylums require an engineering clerk of works, under the direction of their architects and consulting engineers, during the installation of electric lighting machinery, mains, wiring, telephones and heating apparatus, &c., at their new Asylum, Mile End, Colchester. Applicants must be capable of taking charge of the installation when completed. Salary as Clerk of Works £4 per week. Application forms from the clerk to the Committee of Visitors (Mr. Walter Payne Gepp), Essex and Colchester Lunatic Asylums, Chelmsford, to whom applications by April 28.

An assistant is required in the engineer-in-chief's department of the Westminster Electric Supply Corpn., to calibrate and keep in order all instruments and telephones in the company's generating stations. Commencing salary £120 per annum. Applications by the 25th inst. to the Engineer-in-Chief, Eccleston-place, London, S.W.

Mr. T. M. Colson, who has been resident engineer at Hamilton since 1902, has been appointed resident engineer at Surbiton. Mr. G. Salter (Leamington) has been appointed to succeed Mr. Colson.

The Executive committee of the National Physical Laboratory have appointed Mr. J. E. Sears, M.A., to take charge of the work of the metrology division of the laboratory in the place of Mr. H. Homan Jeffcott, who has recently been nominated to the professorship of engineering in the Royal College of Science, Dublin. Mr. Sears, who was formerly at St. John's College, Cambridge, graduated with first-class honours in mathematics and engineering, and is an associate member of the Institution of Civil Engineers.

Mr. E. F. Fleet, assistant signalling engineer, N.E. Railway (Southern Division, York) has been appointed signalling superintendent for the Northern Division at Newcastle, vice Mr. J. Simpkins, resigned.

EDUCATIONAL NOTICES.

Summer School Lectures.—Glamorgan Education committee have arranged short summer courses of lectures during August, as follows: (1) Practical surveying course at Penarth; (2) Engineering course; Mining, mechanical and electrical engineering (laboratory work) and practical mathematics; (3) Metallurgy course: Metallurgy, chemistry and practical mathematics; (4) Teachers' course: Geology (lectures and field work), physics and chemistry (this course has been arranged to meet the requirements of teachers engaged in or preparing for technical work at evening schools or technical schools); (5) Evening lectures for colliery firemen on explosives and shot-firing; (6) Evening lectures on electricity in mines. Courses 2, 3, 4, 5 and 6 will be held at University College, Cardiff, the other courses at the County School, Penarth. Certificates will be issued to successful candidates. Particulars and admission forms from 35, Park-place, Cardiff.

Crystal Palace School of Practical Engineering.—The new courses will commence on 27th inst. New students should attend at the school on the previous day for examination. Prospectus from the Registrar, School of Engineering, Crystal Palace, London, S.E.

Argentina.—Mr. Edwd. Richards has obtained a 30 years' concession for a telephone system to extend from Ultima Esperanza (Santa Cruz Province) to the 30th section in the southern zone of Santa Cruz, with a branch to the Gallegos Punta Arenas telephone line.

Ashton-under-Lyne.—An inquiry was held here last week into the application of the Corporation for permission to borrow £48,424 for extension of the electricity undertaking. It was stated that the loan was required owing to the increasing demand for electrical energy for power by local manufacturers, and the Corporation desire to do everything possible to meet all demands.

Association of Municipal Corporations.—The president (Mr. J. S. Harmood-Banner, M.P.) presided at the annual meeting on Wednesday, and in moving the adoption of the annual report, said that one of the features of legislation, not only in 1909, but for several years past, had been the increasing desire on the part of Government departments to obtain more or less absolute control over local authorities. That was one of the greatest dangers threatening municipal life at the present time, and unless it was faced it would go far towards depriving municipalities of that reasonable degree of independence which they had enjoyed in the past.

Mr. HARMOOD-BANNER said that, while they did not object to reasonable control in such matters as the making of new by-laws and the borrowing of money, the action of Government departments was, according to modern practice, going much too far in that they sought to interfere in matters of administration frequently of a comparatively trivial character, which ought to be left to the persons elected for the purpose, and in that they sought to take the initiative and to force local authorities into action against their wishes. If that policy of centralisation was continued one of the results would inevitably be that sooner or later the men most able and suitable to administer local affairs would cease to become members of councils. They did not hear so much now on the subject of municipal trading from their critics. Most reasonable persons had been convinced by the action of municipalities that, in providing such important public services as the supply of water, electricity and gas, tramways, &c., they had met the public requirements both efficiently and economically.

Australasia.—The "Australian Mining and Engineering Review" contains correspondence in reference to the contract, for which the N.S.W. Government recently invited tenders, for the electrical equipment of a small arms factory at Lithgow (N.S.W.), and for which the tender of the N.S.W. State Dockyard department was accepted.

Mr. G. W. Fuller, Minister for Home Affairs, states that seven tenders were received, and the Fitzroy Dock tender was the lowest. Mr. Cutler, manager of the State Dockyard, is reported to have informed a representative of the "Sydney Morning Herald" that practically all the required machines would be made at the Fitzroy engineering establishment.

The Hon. C. G. Wade, Premier of N.S.W., says it was understood that no N.S.W. firms were likely to tender, and that the Fitzroy Dock tender was the lowest.

Mr. E. J. Erskine, representative of Crompton & Co., and president of the N.S.W. Electrical Employers' Association, asks whether it is not a fact that the boilers and the whole of the electrical plant are to be imported, and states that the contractors who tendered would have quoted lower prices if they had been asked to tender as sub-contractors under the Dock authorities.

Messrs. Haes & Eggers state that they have now before them a tender from a reputable firm of English manufacturers, which is in every way formal, was lodged according to the requirements of the Federal Government in England at the correct time, and is several hundred pounds below that of the Fitzroy Dock tender.

Geelong Council has sealed the agreement with the Melbourne Electric Supply Co. for the construction of electric tramways by the company.

Gisborne, Wairoa, Hastings and Napier (N.Z.) Councils recently appointed a joint committee to report on the question of establishing a joint hydro-electric station at Waikaremoana.

Mr. Forbes-Mackay, Sydney City electrical engineer, reports that the year's income was £118,275 and the net profit £17,898. Mr. Forbes-Mackay recommends the abolition of all meter and demand indicator rents.

The price of 6¾d. quoted by Messrs. Drew & Poole for the supply of 100,000 porcelain insulators of Australian manufacture to the Commonwealth Postmaster-General is stated to be 15 per cent. above the average price paid for imported insulators during the past two years. The material will be Australian, and Messrs. Drew & Poole are about to establish a factory for making insulators.

Barking.—During the year ended March 31 the electricity supply department generated 1,622,485 units, increase 38,772; and 1,374,960 units were sold, increase 37,616. The units used for traction were 293,712, decrease 35,198.

On the light railways the passengers carried numbered 1,292,146, against 1,280,420. Receipts amounted to £3,099, against £3,130. The working expenses have been reduced by about £130, and electricity cost £250 less.

Barnes.—The electrical engineer (Mr. C. S. Davidson) is to invite prices for the supply of 1 mile of distributing cable. The Council have instructed Mr. Davidson to visit the Glasgow electricity works with a view of obtaining information for improving the Barnes electricity undertaking.

Belfast.—The revenue of the tramways department for the year ended 31st March was £203,874, an increase of £8,831; working expenses were £107,574, a decrease of £1,306. The working profit was over £96,000, and the next profit £46,056. The manager (Mr. A. Nance) recommends that this be applied to sinking, depreciation and

Digitized by Google

reserve funds, and to paying off the cost of the Act of 1904, and the debit balance of the net revenue account.

Bethnal Green (London).—The Electricity committee have had again under consideration the question of electricity supply in the borough.

Every authorised undertaker was communicated with, and the Councils of Shoreditch, Hackney, Poplar and Stepney were again invited to submit fresh offers. No company has made any proposal; Poplar and Hackney adhered to their previous offers, and Stepney and Shoreditch Councils made slight modifications in their previous offers. The committee are of opinion that the Council should enter into a contract with Shoreditch for seven years upon the basis of their alternative flat rate scheme.

Birmingham.—The Tramways committee recommend the City Council to extend the tramways system to Harborne and Quinton.

The new station of the G.W. Railway will be electrically lighted throughout.

Bootle.—The Council have decided to adopt electricity for pumping at the waterworks.

Canada.—H.M. Trade Commissioner for Canada (Mr. R. Grigg) states that the Master Builders' Association of Montreal established a permanent exhibition of building materials in that city last year. There are sections for electric light fittings, bells, &c., and for artistic metal work, and it is suggested that this might afford an opportunity for British manufacturers to exhibit their goods and catalogues. Communications to H.M. Trade Commissioner, 120, Board of Trade Building, Montreal, or the Secretary, Department of Permanent Exhibits, Builders' Exchange, Montreal.

Canadian Cable Rates.—It is reported that the Canadian Senate has sent Mr. Lemieux's bill, placing the control of submarine cable rates in the hands of the State, to the Railway Committee. This will ensure the cable companies being in a position to present their case against the threatened interference with their business.

Colchester.—The borough electrical engineer (Mr. A. R. Sillar) has tendered his resignation, and the chief assistant engineer (Mr. Wm. Frisby) has been instructed to undertake control of the department until a fresh appointment is made, and Mr. Frisby and the second assistant (Mr. Buzza) are to act jointly in the working of the station.

Croydon.—The Council have decided to dispose of two dry back marine boilers (now out of use), and to instal two new water tubes boilers, at an estimated cost of £4,500.

Darlington.—The electrical engineer and manager Mr. J. R. P. Lunn has reported to the Electricity committee that it will be necessary to provide additional condensing plant at the electricity works.

Devonport.—The Council have applied for sanction to a loan of £7, 061 for extending the electricity mains in the Pennycomequick district.

A number of the electrical staff have been granted increased salaries and wages, including Mr. W. F. Stamp, assistant electrical engineer, whose salary has been increased to £180.

Dunfermline.—The Queen Anne United Free Church is to be wired.

Electric Carriages in Hyde Park.—Licences and badges will be issued by the Commissioners of Works and Public Buildings for the admission of electric carriages to Hyde Park between 4 p.m. and 7 p.m. in the months of May, June and July.

Electric Plant for Oil Cleaning.—At the meeting of the Pacific Oilfields (Ltd.) on Friday, the chairman (Mr. A. B. Williamson) said that

Under a contract the company had been delivering oil from one of their properties to buyers who had laid their pipe-line to their tanks. These buyers had at first expressed entire satisfaction in regard to its quality and freedom from impurities, but later objection was taken on the score of an excessive percentage of water in the oil. Finally, it was intimated that they could not accept further deliveries in that condition. The presence of water in microscopic globules was suddenly discovered in their oils and in other wells in the neighbourhood, and it was possible it might as suddenly disappear. Local experts apparently believed that it had been forced into the oil by gas and other pressures and that it was not the result of ineffective shutting off of water in the wells. Their buyers, however, had signified their willingness to accept again if they could reduce the water to a moderate percentage. Unable to do anything in that regard at short notice, and their tanks soon being filled with oil which they could not deliver, the management had to shut down the wells just as the fourth well was completed, so it had not been pumped yet. Under those circumstances, it was decided to instal an electrical cleaning plant. Their agents and field manager had made careful investigation and had seen the proposed plant in satisfactory operation in other fields, where it had met with entire success in clearing the oil of that form of water. The water was found in such microscopic globules that it would not collect and free itself by the usual gravitation process. The electrical plant was now being constructed, and it was expected to be completed in April current. It would serve other useful purposes, such as lighting the camp, supplying power for drilling the wells, and operating a lathe and pipe threader, which would always be an economy of time and money.

Exhibition.—The Brussels International Exhibition will be opened to-morrow (Saturday).

Fatality.—On Wednesday Harry Calladine was killed while working an electric coal-cutting machine at South Wingfield Colliery, Alfreton.

Felixstowe.—An inquiry was held on Tuesday into the application of the Council for permission to borrow £4,500 for additional plant for the electricity works.

Fire.—A fire in the electrical engineering works of Mr. Edwd. Dewhurst, at Preston, occurred last week, and although it was quickly subdued, the damage is estimated at about £400. The fire began with the ignition of wood by an emery wheel.

Gillingham.—At the inquiry held last week into the Council's application for sanction to borrow £3,000 for a Diesel oil-driven set, &c., the inspector (Mr. H. Ross Hooper) pointed out that separate ledger accounts must be kept for each loan. He must have the accounts put in order from March, 1908, and, therefore, the inquiry was adjourned.

Grimsby.—The borough electrical engineer (Mr. W. A. Vignoles) reported to the Lighting committee on Monday that during the past quarter there had been an increased consumption of 86,492 units of electric current compared with the previous quarter.

Mr. Vignoles submitted a scheme for stimulating the use of arc lamps by tradesmen. He stated that the initial cost and short life of arc lamps deterred many traders who would like this system of exterior lighting from embarking upon it, and he suggested that the committee should supply arc lamps on the hire purchase system, or by simple rental. The committee decided to adopt the scheme.

Hammersmith (London).—The existing 100 c.p. lamps in Woodlane are to be replaced by 200 c.p. lamps.

Holborn (London).—The Metropolitan Electric Supply Co. has reduced the charge for electric energy in connection with the lift and fans at the Council's offices from 3d. to 2d. per unit. The concession is to date from Jan. 1 last and is also to apply to power used in the stone yard.

Hornsey (London).—There are over 1,720 consumers of the electricity department and the equivalent of over 91,000 30-watt lamps is connected to the mains.

India.—It is stated that the Calcutta Electric Supply Corpn. intend to transmit current at 6,000 volts pressure from their Ultadanga station in the north of Calcutta to the riverside warehouses and presses.

The report of the Irrigation Branch of the Punjab Public Works Department for 1908-9 states that a new machine shop 200 ft. by 80 ft. is under construction at the Upper Bari Doab Canal Central workshops, that the whole of the machinery therein will be driven electrically, a 10 ton electric travelling crane will span the central bay, and that a new power house has been erected.

Inquest.—An inquest was held on Saturday into the death of Llewellyn Evans, electrical engineer, which occurred at the Birmingham Tame and Rea District Drainage Board's sewage disposal works, Bromford, on 13th inst.

Dr. F. W. CLARK, who was called to the works immediately after the accident, said he found the mark of a burn on the toe of the left foot and a corresponding mark on the left boot. He was informed that Evans had received an electric shock, and he ascribed death to the shock, which had arrested the heart's action.

LOUIS MOUNTFORT, electrical engineer in the service of the Drainage Board, said Evans had been employed at the Bromford works as chief operating electrical engineer for 2½ years. On April 13 he and two other electricians were testing a newly-installed motor. At the time of the accident the machinery had been under test at full load for six hours. One of the principal objects of the test was the fixing of a measuring instrument to gauge the quantity of current, and it was on this work chiefly that Evans was engaged. Evans expressed the opinion that the voltage (6,000) being employed would damage the instrument. A consultation on that point was held, and resulted in a determination to allow the current to pass through the instrument. Evans left his (witness's) sight at that point, and a moment later he heard an exclamation, and Evans was found lying unconscious near the instrument. Artificial respiration was tried, but without avail. He conjectured that Evans went to make the alteration in the current he and his colleagues had decided upon, and, forgetting that the current was on, touched the live wire.

The CORONER: Did you know that the switches were not disconnected and that the current was on?—Yes. And Evans knew a few minutes before. His going to the instrument instead of to the switch indicated that he must have forgotten the main switches were closed. He was wearing a rubber glove, but that would be no protection against 6,000 volts. No one actually saw Evans killed, because he went behind the switchboard, apparently to the instrument. I consider that momentarily he forgot the switches had been put in, and that he went straight back to his instrument without seeing whether they were in or out.

There is no suggestion that any part of the machinery was out of order?—Not in the least. Nor was there any neglect to provide protective appliances to make everything safe.

Replying to a question, witness agreed that an insulated floor might produce a false sense of security. It is better that a man should realise fully the danger of approaching a live wire carrying 6,000 volts, and there should be no degree of safety in the presence of it.

Mr. H. Kemp (Mr. Evans's assistant) and Mr. H. W. Fisher, engineer in the employ of Messrs. Crompton & Co. (who supplied the motor) agreed with Mr. Mountfort.

The jury returned a verdict of accidental death.

Japan-British Exhibition.—The President (the Duke of Norfolk) asks us to impress upon all participating in the British section of this Exhibition the necessity of taking advantage of the facilities afforded by the administration in order to have their exhibits completely installed in ample time before the opening early in May. The Japanese have already made great progress.

The Prince of Wales has consented to perform the opening ceremony.

Leeds.—At the meeting of the Tramways and Electricity committee on Monday it was reported that during the year ended March 31 there had been an increased revenue. A surplus of £46,000 had been estimated, but this had been exceeded by about £9,000. There will be about £55,000 for relief of rates after paying £18,528 for rates and taxes, &c.

The general manager of the city tramways (Mr. J. B. Hamilton) reported that the past year had been more prosperous than anticipated, and the amount of the profit was £55,000.

Litherland (Lancs.)—The electric lighting order has been extended for a year.

London County Council.—On Tuesday sanction was given to Stepney Council to borrow £7,150 and £33,500 for the electricity supply.

Special Car.—The Highways committee reported having constructed by direct labour the body of a specimen electric tramcar of special pattern for use on steep gradients. The Board of Trade had now agreed to the use on the Highate-hill tramways of double-deck cars with or without roof covers, when fitted with a special slot-brake. They had arranged for a roof cover to be fitted on the special car and also for certain modifications to be made to the underframe of the car in connection with the braking arrangements.

Purchase of Electric Lighting Undertakings.—The Highways committee stated that they reported in October, 1909, with reference to agreements proposed to be entered into, under the London Electric Supply Act, 1908, between the London Electric Supply Corpn. and the St. James' & Pall Mall Electric Light Co., and between the London Electric Supply and the Westminster Electric Supply Corpns., and the Council decided to ask the Board of Trade, in the event of their deciding to approve the agreements, to arrange for the following amendments to be made: (i.) The insertion of a clause to provide for the termination of the agreements in 1915, unless in the meantime legislation shall be passed constituting the Council the purchasing authority of the undertakings of the Westminster Electric Supply Corpn. and the St. James' & Pall Mall Electric Light Co. (ii.) The insertion of such a clause as may be considered necessary to ensure that the interests of the consumers in the areas affected by the agreements shall be fully safeguarded.

The Board of Trade have now forwarded the draft of the agreement proposed to be entered into between the London Electric Supply and the Westminster Electric Supply Corpns., amended with a view to meeting certain of the points raised by the Council, but with reference to the Council's suggestion that the agreement should be terminated in 1915 the Board stated that it was not prepared to introduce such a clause, because it would destroy the whole basis of the agreement, and it was further pointed out that the Board had introduced a bill into Parliament in the present session for transferring the power of purchase to the Council. The agreement dealt with one undertaking (the London Electric Supply Corpn.) which was purchasable under the 1908 Act, while the undertaking of the Westminster Electric Supply Corpn. was not yet purchasable. The assurance of the Board as to the introduction of legislation did not, the committee thought, quite meet the Council's views, and the committee are of opinion that the Council should press for the insertion in the agreement of the provision desired.—It was agreed to communicate to the Board of Trade in the terms of the report.

Manchester.—On Tuesday the Tramways committee approved the estimates for the current year, and provision is made for the payment of £60,000 in relief of rates, against £75,000 last year. The decrease is due to the fact that the committee have to meet additional expenses, including payment of half-wages to sick workmen, higher rates, &c.

The Electricity committee have had before them the accounts for the year ended March 31. The net surplus is £35,220, of which £12,000 had already been paid over in aid of rates, and the balance of £23,220 was now placed to renewals account. It was reported that the sales had exceeded all previous records, notwithstanding the fact that there had been a reduction of more than 1,000,000 units in the consumption for traction. On electric lighting there was only an increase of about 500,000 units, but the power and heating sales showed an increase of 5,000,000 units.

Marylebone (London).—The Electricity committee, in submitting the annual estimates, report that as far as can at present be ascertained, the total sales to private consumers for the year ended March 31 last will amount to 10,316,000 units (an increase of 16 per cent.) and the average price to 3·63d. (a decrease of 9 per cent.).

For the current year the increase in units has been put at half last year's increase (8 per cent.), and there will probably be a further diminution of prices to the extent of 0·28d. per unit, or 8 per cent. This gives an estimated increase of 825,000 units, compared with nearly 1,500,000. A substantial increase has taken place in public lighting owing to the three schemes for converting to electricity the whole of the gas lamps in the borough. It is calculated that the increased units for street lighting will amount to 440,000. In estimating cost of generation, distribution, management, &c., the balance costs for the half-year to December have been taken as a basis and it has been assumed that all additional sales during the year will not exceed a total cost of 0·5d. per unit. The general manager (Mr. A. Hugh Seabrook) is of opinion that the sales department will pay its way after debiting all expenditure properly chargeable against it. After reducing the capital liabilities by £37,915 the committee estimate that there will be a surplus on the year's working of £8,602.

Mold.—The Lighting committee are to consider an electric lighting scheme submitted by a Leeds firm.

New Malden and Coombe.—The Council have informed Kingston Corporation that they are prepared to consider proposals with reference to the supply of electricity to residents in Coombe.

Obituary.—We regret to record the death of Mr. Augustin Gifford Palgrave, M.A., electrical engineer (son of the late Sir Reginald Palgrave, K.C.B., for many years clerk to the House of Commons). Mr. Palgrave (who was under 40 years of age) was born within the precincts of the Houses of Parliament and educated at Marlborough and at Merton College, Oxford. Deceased, who leaves a widow and two children, resided at Withington, Manchester, until recently, when he moved to Newcastle-under-Lyme.

We regret also to record the death of Sir Samuel Black who was town clerk of Belfast for over 30 years. During his tenure of office Belfast Corporation established electricity works, municipalised the tramways, and carried out many other extensive improvements.

Oswaldtwistle.—The Council have resolved to apply for an electric lighting order.

Penzance.—The Council have instructed the Electric Lighting committee to report upon a communication received from Mr. W. T. Pressland who is acting for the Cornwall Electric Power Co., and has offered to take a transfer of the Penzance Electric Lighting Order.

Presentations.—Fleetwood electricity staff have presented a smokers' cabinet to Mr. W. Smith, who is leaving for Liverpool.

Mr. T. M. Colson, resident electrical engineer at Hamilton, has been presented by officials of the Hamilton Corporation with an inlaid Sheraton clock, and an aneroid barometer, on his leaving to take up a similar position at Surbiton.

Saltwood (Kent).—Elham (Kent) Rural Council have consented to electric current being supplied to consumers at Saltwood by the Folkestone Electricity Supply Co.

Shoreditch (London).—Mains extensions are to be made at a cost of £497, and £400 is to be spent in providing a further stock of meters and indicators.

Smoke Nuisance.—Before the Oldham magistrates on Wednesday the Electricity Department were summoned by the Health Department of Oldham Corporation for alleged nuisance by allowing black smoke to issue on two occasions from the local electricity works.

It was stated that experiments were being carried out with a view to doing away with the nuisance. This was expected to cost about £2,500. A fine of £1 and costs was inflicted in each case.

Southampton.—The tramways manager has been authorised to purchase controller regulators at a cost of £137. 10s., so as to make it impossible for a motorman to rush his car at starting.

Stepney (London).—In connection with experiments to reduce the smoke emitted from the chimney at the Whitechapel generating station, arrangements were made some time ago with the Crosthwaite Fire Bar Synd. to fix on trial for three months the Crosthwaite furnace to one of the hand-fired boilers. The engineer and manager (Mr. W. C. P. Tapper) now reports that the result of the experiment has been quite satisfactory, and the apparatus is to be purchased at £145.

Street Boxes and District Surveyors' Fees.—Southwark (London) Council having recently raised the question of district surveyors' fees, and Islington has written expressing the opinion that the exemption of street boxes from the operation of the London Building Act should be brought under the notice of the L.C.C.

Whitehaven.—The Board of Trade are to be asked to grant an order to supply electricity in the parish of Hensingham.

Digitized by Google

Wireless Telegraph Notes.—Marconi's Wireless Telegraph Co. announce that their trans-Atlantic service between Europe and America will be re-opened to-morrow (Saturday), and that from that date the company will maintain a 24-hour telegraphic service for commercial and other purposes. The company's offices are Watergate House, York-buildings, Adelphi, London, W.C.

The expert committee appointed to consider the tenders received for the erection of high power wireless telegraph stations at Sydney and Fremantle have reported to the Commonwealth Postmaster-General (Sir John Quick), who has decided that the tenders (with one exception) have complied with all the requirements of the specification. The successful tenderers have to erect the plant on sites in or near Fremantle or Sydney to be determined by the Government, and have also to provide supervision in working the plants for three months after erection, and the maintenance of the works for 12 months in working order. The Advisory Board recommend the acceptance of the lowest tender, subject to certain conditions, and Sir John Quick has adopted this advice, conditioning that there shall be some undertaking as to the nature of the labour to be employed during the probationary period of supervision and maintenance.

An Institute of Wireless Telegraphy is reported to have been formed in Sydney, N.S.W., with a view to facilitating conferences between investigators and inventors, and protecting legitimate experimenters.

A report from Eureka, California, states that the North Pacific Co.'s steamer "Santa Clara" sank four miles from that place on April 12. A wireless message brought a tug which rescued the whole of the 95 souls on board the steamer, which ultimately went down.

Yarmouth.—Application is to be made for sanction to borrow £500 for h.t. and £3,000 for l.t. mains.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

NEWPORT (Mon.) Electricity committee invite tenders for supply and erection of a 1,000 kw. double-current turbo-generator or, alternatively, a 1,000 kw. or 1,500 kw. turbo-alternator, together with surface condenser. Specifications, general conditions and forms of tender from the borough electrical engineer and tramways manager (Mr. H. Collings Bishop). Tenders, addressed to the Town Clerk, by first post, Monday, May 2. See also an advertisement.

LEEDS City Council invite tenders for supply of 5¼ miles of 0.15 sq. in. three-core cable, suitable for working pressure of 6,600 volts. Tenders to the town clerk (Mr. Robt. E. Fox), by 10 a.m. Monday, May 9. Specifications and conditions from the manager of the electric lighting department (Mr. H. Dickinson), 1, Whitehall-road, Leeds. See also an advertisement.

Tenders are invited up to June 1, for the supply of eight sections of common battery switchboard to the Postmaster-General's Department, NEW SOUTH WALES. Tender forms, specifications, and general conditions may be obtained at the Commonwealth offices, 72, Victoria-street, London, S.W. See also advertisement.

Tenders are invited up to June 8 for the supply of protectors, switchboards (small) and common battery telephones to the Postmaster-General's Department, QUEENSLAND. Tender forms, specifications and general conditions may be obtained at the Commonwealth offices, 72, Victoria-street, London, S.W. See also advertisement.

Tenders are invited (up to May 17) for supply to the Postmaster-General's Department, VICTORIA, of 50 coin attachments. Tender forms and specifications from the High Commissioner's Office, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are required by June 8, 1910, for the supply of six sections of common battery switchboard and equipment jumper wire and cable to the Postmaster-General's department in QUEENSLAND. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W.

Tenders are invited, up to May 18, for the supply of paper insulated lead-covered and brass ribbon taped cable to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See an advertisement.

The Deputy Postmaster-General, MELBOURNE, will receive tenders until 3 p.m. May 17 for supply of 1,010 reinforced concrete telegraph poles, preferably of Australian cement. Local representation necessary. Specification from Commonwealth office, London.

LITTLEBOROUGH Urban District Council invite tenders for the supply and laying of h.t. feeder cables, l.t. distributors, roadwork, &c., for private lighting, and transformer kiosk, with transformers and equipment and switchgear in substation. Copies of specification, forms of tender, &c., may be obtained from the clerk to the Council, Mr. Geo. H. Wild. The works are to be carried out in accordance with plans and specifications, which may be seen at, but not obtained from, the offices of the consulting engineers, Messrs. Hawtayne & Zeden, 9, Queen-street-place, London, E.C., from whom further information can be obtained. Tenders to the Clerk to the Council, Council Offices, Littleborough, near Manchester, by May 2.

WHITWOOD Urban Council invite tenders for copper cables, steel and wooden poles, supports, arms, insulators, &c., watertight street light fittings, meters, switchboard, instruments, &c. Specifications from Mr. H. Marsden, Electricity Works, Honley, and tenders to Mr. V. Hulme, County Chambers, Castleford, Yorks., by April 28.

WEST BROMWICH Electricity committee invite tenders for supply, delivery and erection of a 750 kw. d.-c. turbo-generator and surface condenser. Specification, general conditions, forms of tender, &c., from the borough electrical engineer (Mr. W. A. Jackson), Electricity Works, West Bromwich. Tenders to the Chairman of the Electricity committee, Town Hall, West Bromwich, by May 2.

The SECRETARY OF STATE FOR WAR invites tenders for the supply of two plants for the production of hydrogen and oxygen by the electrolysis of water at the Balloon Factory, South Farnborough, Hants. Forms of tender from the Director of Army Contracts, War Office, Whitehall, London, S.W., where tenders are to be delivered by noon of May 4.

HESTON and ISLEWORTH Council want tenders by noon May 11 for extension of engine room, and for supply of 250 kw. generating set (high-speed engine direct coupled to c.c. 500-600 volt generator), piping, ejector condenser, machine tools, &c. Specifications, &c., from the Engineer, Electricity Works, Bridge-road, Hounslow.

LAUNCESTON (Tasmania) Council want tenders by 4 p.m. June 13 for overhead electric equipment for tramways, and by 4 p.m. June 27 for synchronous motor-generators, &c., and battery, reversible booster, &c. Specifications, &c., from the Town Clerk.

BRISTOL Docks committee want tenders by noon April 30 for one year's supply of stores, including arc lamp carbons, incandescent electric lamps, metals, oils, &c. Forms of tender from the Engineer, Cumberland Basin, Bristol.

IPSWICH electric supply department want tenders by April 27 for supply of about ¾ mile 0·3 sq. in. concentric feeder and about the same quantity of multicore cable. Specifications, &c., from the Borough Electrical Engineer.

LONDON County Council want tenders by 11 a.m. May 3 for roadwork and platelaying required for reconstruction on the conduit system of tramways in Bermondsey and Deptford. Specifications, &c., from the Chief Engineer.

LONDON County Council require tenders by 11 a.m. May 3 for supply of 4,800 steel tyres for driving wheels, and 1,600 for pony wheels of tramcars. Forms from 62, Finsbury-pavement, E.C.

LONDON County Council also require tenders by 11 a.m. May 4 for the electric lighting of Fairclough-street and Amberley-road schools. Specifications, &c., from the Chief Engineer, Spring Gardens, S.W.

Tenders are wanted for the electric lighting of St. John's Church, ROUGHTOWN, near Manchester. Tenders to the Vicar and Churchwardens, Roughtown Vicarage, Mossley, by May 2.

SHIPLEY Council want tenders by 10 a.m. May 3 for supply of steel girder tram rails and fish plates. Specifications, &c., from Mr. W. H. Dawson, Shipley.

HENDON Council want tenders by 5 p.m. April 25 for the electric lighting of the Council Offices, The Burroughs, Hendon. Specification may be seen at the Council Offices.

The Consejo de Administracion del Puerto de MONTEVIDEO (Uruguay) require tenders by 3 p.m. July 4 for supply of 20 electric cranes.

VASLUI (Roumania) Municipality require tenders by May 25 for erection and equipment of electricity works.

The Turkish Ministry of Commerce and Public Works require tenders by May 28 for a concession for electricity supply works at CONSTANTINOPLE. Deposit of £9,000 required with tender. Local representation necessary. Specification (in French) may be seen at 73, Basinghall-street, London, E.C.

ANTWERP Council want tenders by May 9 for supply of electrical appliances for the town workshops at the new North Docks. Conditions, &c. (price 5d.) from the Hotel de Ville.

Digitized by Google

The SPANISH GOVERNMENT require tenders by Nov. 7 next for construction of a single-track electric or steam strategic railway from Badajoz to San Vicente de Alcantara, and, by Feb. 6, 1911, for a similar line from Badajoz to Fregenal. The contracts are open to Spanish firms only, but material may have to be purchased from abroad.

SALAMANCA (Spain) Municipal Council want tenders by 1 p.m. May 13 for the provision of electricity supply works. Local representation is necessary.

TENDERS RECEIVED AND ACCEPTED.

Blackburn Council have accepted the following tenders :—

L. Andrews & Co., armature insulating varnish; Boardman Bros., cotton waste; Baxter & Caunter, screwed tubes for inside wiring; P. W. Blackwell & Co., P. and B. insulating tape; British Insulated & Helsby Cables, house service fuse boxes; British Westinghouse Co., linen tape, shellac, motor starting switches; Burrows & Garland, metallic joint-rings and ironware; Cresswell's Asbestos Co., packing, asbestos sheet, asbestos millboard and abestos string; Eckstein, Heap & Co., ceiling roses, switches (10 amperes); Jas. Ferguson, machine screws; General Electric Co., ebonite sheet and rod; W. T. Glover & Co., diatrine tape; W. T. Henley's Telegraph Works Co., waterproof tape; India Rubber, Gutta Percha & Telegraph Works Co., indiarubber solution, self-adhesive compound tape; John Lang, iron castings, fire-bars, pipes, &c.; Mercer Bros., fish-glue, nails, hammers, &c.; Micanite & Insulators Co., micanite plate; Siemens Bros. & Co., ozokerit tape, non-hygroscopic tape, porcelain fuses, &c.; Spicer Bros. (Ltd.), red fibre sheet and press-spahn sheet; Wm. Stones & Sons, teak boards, baywood and pine; J. H. Tucker & Co., tumbler switches and lampholders; Watlington & Co., P. & B. insulating paint; Booth & Openshaw, resin, wax, paints, asbestos paint, turpentine, &c.; and Vacuum Oil Co., oils.

The following tenders have been accepted by London County Council :—

Hurst, Nelson & Co. (lowest tender), for brass fittings for tramcars, £186. 11s. 11d. (nine tenders received, highest £305. 17s. 7d. Chief officer's estimate, £230.)

Hurst, Nelson & Co. (lowest tender), for 90 sets of operating gear for car windows, £668. 7s. 6d. £7. 12s. 6d. per set for bogie cars and £6 per set for single-truck cars. (Eight tenders; highest £28. 10s and £23. 10s. per set. Chief officer's estimate, £1,125.)

Wm. McGeoch & Co. (lowest tender), for 545 roof light fittings for 90 cars, 5s. 5d. each, less 2½ per cent. (nine tenders; highest 9s. 7d. Chief officer's estimate £150.)

Deptford Engineering Co. (lowest), for six conduit cleaning trucks, £152. 9s. (Six tenders; highest £357. 7s. 7d. Chief officer's estimate £250.)

J. G. Ingram & Son (lowest), for 500 moulded rubber plough bases and 916 plough leads, 37s. 6d. each for bases and 3s. 3d. each for leads. (Four tenders; highest for bases £4. 15s. each and for leads 11s. 2d. each. Chief officer's estimate, £1,280.)

The following tenders have been accepted by Southampton Council in connection with the tramways :—

John Douglas, construction of tramways from Clock Tower and Northam Toll Bridge, £2,816. 11s. 8d.; ; Walter Scott (Ltd.), 400 tons tramway rails, £7 per ton; Imeson, Finch & Co., 130 steel poles, £3. 19s. 9d. each and 130 c.-i. pole bases and 150 finials, £111. 17s. 6d.; Edgar Allen & Co., 10 pairs points, £34 per pair, 10 sets crossings, £13 each, and 10 tons rails for curves, £43 per ton.

The tender of the British Thomson-Houston Co. has been accepted by Southampton Council for annual supply of lamps at £60; and the tenders of the following for annual supplies of stores have also been accepted: Lankester & Son, Cammel, Laird & Co., McWhirter, Roberts & Co., Armstrong, Stevens & Son, Wm. Dibben, Flack, Ellis & Co., Summers & Payne, Shalders & Davis, Jas. Freemantle & Son, and A. Duckham & Co.

Marylebone (London) Council have accepted the following tenders:

W. T. Henley's Telegraph Works Co., rubber tubing; Pryke & Palmer, Chatterton compound, Para rubber strip, fire resisting tape, &c.; Siemens Bros. & Co., black adhesive tape, rubber gloves and plain rubber mats; Pooley & Austin, white silesian tape; Anti-Attrition Metal Co., gun-metal, copper and brass; H. W. Gilbart, casing and capping, match-lining and creosoted troughing; General Electric Co., capping; C. Jennings & Co., casing and capping, meter boards and battens; Howard Bros. & Co., match-lining and American white wood.

Hammersmith (London) Council have accepted the following tenders for annual supplies: Sloan Electrical Co., Conradty carbons, H. G. Mayer & Co., Stella, (enclosed type) carbons; Edison & Swan, electrical goods (£36. 7s. 5d.); Hobdell, Way & Co., boiler covering, &c. (£66. 6s.); Bruce Peebles & Co., brushgear for two 400 kw. motor generators (£21. 12s. for two sets).

Gravesend Council have accepted the following tenders:

Chloride Electrical Storage Co., overhauling and repairing traction storage battery, £374. 14s.; British Thomson-Houston Co., lamp stores; Sutton & Co., cable troughing; Bastian Meter Co., Electrical Co., Ferranti (Ltd.), and British Thomson-Houston Co., meters.

Stalybridge, Mossley, Hyde and Dukinfield Tramways and Electricity Board have accepted the tender of Ed. Bennis & Co. for two mechanical stokers, and that of Graham, Morton & Co. for a coal conveyor and bunkers.

Grimsby Corporation have accepted the tender of the Jandus Arc Lamp Co. for supply of 80 flame arc lamps with line switches and resistances for £662. The lowest tender submitted was £307, the highest £789.

Chichester Council have accepted the tender of the local electric lighting company for lighting the city for five years at £3. 5s. per lamp per annum. Gas lighting has been displaced.

Whitehaven Council have accepted the tender of Babcock & Wilcox for a boiler and that of the Phœnix Dynamo Mfg. Co. for a 2 H.P. motor for driving the mechanical stokers.

Bootle Council have accepted the tender of the Northern Electric Co. for wiring the girls' secondary school at £89. 10s.

Southwark Council has accepted the tender of the Electrical Co. for a 10 H.P. motor at £36. 8s. 2d.

Barking Council have accepted the tender of the Union Cable Co. for cable at £47. 8s.

Lowestoft Council have accepted the tender of W. G. Murrin for "free" wiring up to a total of 200 lamps at 8s. 8d. per point.

Aberdare Council have accepted the tender of D. T. Davies for the erection of electricity station buildings at £562.

"Lea" Recorders.—The "Lea" Recorder Co., 28, Deansgate, Manchester, have recently received a number of orders for "Lea" recorders (for home use and export), including the following amongst many others :—

Glasgow Corporation Electricity Works, Stockport Corporation Sewage Works, Brighton Corporation Electricity Works, General Post Office, London (three sets), J. G. White & Co., Cardiff Corporation Electricity Works, Ryde pumping station (Australia), London Hydraulic Power Co., Halifax Corporation Electricity Works, Adelaide (Australia) Municipal Tramways, West Bromwich Corporation Electricity Works, Broken Hill South Silver Mines, Australia, Sydney (Australia) City Council, Cheltenham Sewage Works, Cheltenham, E. Hulton & Co., Manchester, Electricité de Paris, &c.

Government Contracts.—The following tenders have been accepted by Government Departments :—

War Office :—Barton & Sons, Credenda Conduits Co., General Electric Co., Nettlefold & Sons and Perfecta Seamless Steel Tube & Conduit Co., conduit fittings; Lancashire Dynamo & Motor Co., motors; Electric Construction Co., motor-generators and switchgear. *India Office* :—Bullers (Ltd.), insulators; Siemens Bros. & Co., manganese blocks. *General Post Office* :—Western Electric Co., indiarubber and cotton core cable; Johnson & Phillips, Western Electric Co. and British Insulated & Helsby Cables, paper core cable; India Rubber, Gutta Percha & Telegraph Works Co., submarine cable; Western Electric Co., loading coils; British Insulated & Helsby Cables, flexible cords and copper wire; T. Bolton & Sons, Elliott's Metal Co., R. Johnson & Nephew, Shropshire Iron Co., F. Smith & Co., and Wilkes, Son & Mapplebeck, copper wire; Stanley Bros., earthenware ducts; Colley's Patents (Ltd.) and Waterlow & Sons, telegraph paper; British L. M. Ericsson Mfg. Co., telephones; A. & P. Stevens, four electric lifts at Newcastle-on-Tyne, Western Electric Co., local telephone exchange equipment installation at Kirkintilloch.

Commonwealth Tenders.—The Australian Postmaster-General has accepted the following :—

The tender of Drew & Poole for 100,000 porcelain insulators of Australian manufacture at 6¾d. each; Davies, Shephard & Co., for fuses, plugs, terminals, glass cells, porous pots, sal ammoniac and Leclanché zincs; Standard Cable Mfg. Co. for wire; and Scheele & Gibbes for glass cells, sal ammoniac and Leclanché porous pots and zincs.

The following tenders have also been accepted by the Postmaster-General's department :—

Victoria.—J. Bartram & Son, g.-i. wire; R. Johnson, Clapham & Morris, g.-i. and h.-d. copper wire; British & Foreign Indent Co., 5,500 porcelain insulators.

N.S.W.—W. T. Henley's Telegraph Works Co. for submarine telephone cable; Jones Bros., coal; Jas. Paton & Co., table magnets, telephone sets and protectors; Lawrence & Hanson, common battery wall telephones; British Insulated & Helsby Cables, common battery table telephones.

Queensland.—Jas. Paton & Co., plugs; Western Electric Co., lamp signalling switchboard for Toowoomba Post Office, relays and rheostats; Siemens Bros. Dynamo Works, lead-covered cable; G. Wills & Co., 60,000 porcelain insulators; Brabant & Co., jointing sleeves and g.-i. wire; British Insulated & Helsby Cables, copper tapes and binders, phosphor bronze, copper v.i.r. lead-sheathed and tinned copper wire, D.P.B. receivers and cords, and condensers; India Rubber, Gutta Percha & Telegraph Works Co., phonopores and phonopore carriers and detectors; Brisbane Electrical Co., Morse keys and trembling bells; Perry Bros., solder, staples and washers; Rich & Co., g.-i. wire; Webster & Co., gal. steel wire; Lawrence & Hanson, ammeter and chronoscopes; Jas. Paton & Co., fuses in glass tubes; Hippisley & Waddell, coin attachments.

Western Australia.—J. M. Ferguson, table telephone sets.

Tasmania.—British Insulated & Helsby Cables, paper-insulated cable, bronze and v.i.r. copper wire, Morse sounders and cords; Western Electric Co., lead-covered, silk and cotton-insulated cable; W. T. Henley's Telegraph Works Co., webbing; India Rubber, Gutta Percha

Digitized by Google

& Telegraph Works Co., terminal screws, &c.; Siemens Bros. & Co., Morse keys and relays; International Electric Co., switches and switchboards; H. K. Fysh & Co., dry cells; Scheele & Gibbs, porcelain tubes; Shiner & Co., c.-i. brackets; Ringdahl & Co., coin attachments.

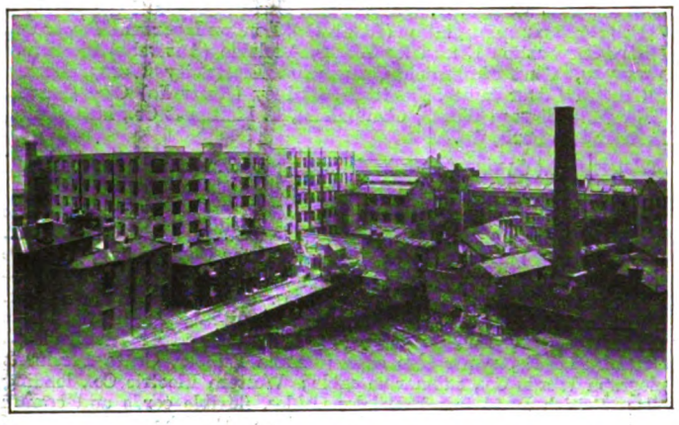
Sale by Auction.—Messrs. Fuller, Horsey, Sons & Cassell have been instructed to sell by auction at H.M. Dockyard, Chatham, on Tuesday, May 10 and following days some old and surplus stores, including 3,000 tons mild steel and steel and iron scrap, also quantities of wire rope, steel tubes, lead and zinc ashes, brass borings and scrap metal, electric cable and electrical gear and stores, boilers, machine tools, &c. May be viewed three working days prior to and on morning of sale. Catalogues (6d. each) at the Dockyard, or of Messrs. Fuller, Horsey, Sons & Cassell, 11, Billiter-square, London, E.C. See also an advertisement.

For Sale.—In another column an electric light and power undertaking is advertised for sale as a going concern.

Machine Tools for Sale.—Messrs. Price & Belsham, 52, Queen Victoria-street, London, E.C., advertise some lathes for sale.

Factory Premises for Sale.—Mr. F. Warman, 52, Chancery-lane, London, W.C., has for sale some well-equipped factory premises in Reading. See an advertisement.

Osram Lamp Development.—The development of the Osram lamp is well shown in a letter the General Electric Co. have received from Messrs. Bull & Barton in regard to the present pay roll at the Osram lamp works. On March 13, 1910, it appears that the number of persons employed in manufacturing Osram lamps at Hammersmith (including the staff and managers) was 946. The Works, in which nearly 1,000 people are employed, are shown in the accompanying illustration.



THE OSRAM LAMP WORKS, HAMMERSMITH.

"Tantalum" Lamps on a Merry-go-round.—Tantalum lamps, as we have many times shown, are used in a variety of places. This week we illustrate Tantalums on a merry-go-round (at St. Kilda Beach, Melbourne, Australia), showing the effect of Tantalum illumination at night time, and at the same time demonstrating that they will withstand severe vibration. Residents in provincial towns are familiar at certain seasons of the year with the ear-splitting noises of these delights of gay and giddy youth, and all will agree that the din and vibration is "heavy." Tantalums seem to thrive in these surroundings.

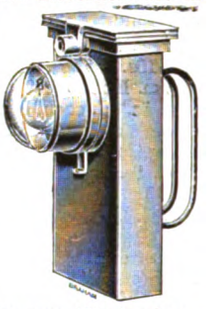
Garcke's Manual of Electrical Undertakings.—We have received a copy of the 14th edition of this "Manual" which appears to have been carefully revised. All the well-known features of the publication have been retained, and complete financial and other particulars relating to about 3,000 electrical undertakings are given, their classification being the same as in previous years, as follows: (I.) Electric Lighting, Power and Traction, (II.) Telegraphs and Telephones, (III.) Manufacturing and Miscellaneous, (IV.) Colonial and British Possessions, (V.) Directories of Officials, including Chairmen, Managers and Secretaries, members of Electric Lighting and Tramway committees, and Electrical Contractors, and (VI.) Index of Undertakings and list of other Electrical Undertakings registered since 1896. The "Progress of the Year" section contains a general survey of the year's work, but the main portion of the book is made up of particulars relating to all joint-stock electrical companies and municipal electrical undertakings. These particulars include the latest accounts in full, comparative tables of progress and other statistical data, information about the constitution of the undertaking, &c., also dividends paid and Stock Exchange quotations, and names of directors, members of committees and other officials. The "Manual" is published by the Electrical Press (Ltd.), 57 and 58, Strand, London, W.C., at 21s. nett.

CATALOGUES, &c.

ALUMINIUM 'BUS BARS.—We have received from the British Aluminium Co. a copy of a pamphlet containing a great deal of interesting information regarding the use of aluminium for 'bus-bars, machine and feeder connections.

ARCTIC VENTILATING FANS.—The Wilson-Wolf Engineering Co., of Bradford, send us a section of their new catalogue dealing with Arctic ventilating fans for direct current. Illustrations and details are given of the complete range of fans up to 72 in. in diameter, together with suitable regulators and other accessories.

LEA RECORDER.—The Lea Recorder Co., of Manchester, forward a leaflet illustrating their well-known recorders, and giving some details of the work carried out by the Company. An interesting list on the back of the pamphlet shows where Lea Recorders are in use. We can advise station engineers to take the first opportunity of becoming acquainted with this useful piece of apparatus.



ELECTRIC SAFETY LAMP.—A new type of electric safety lamp has recently been put on the market by the Bristol Electric Safety Lamp Works, of Westminster, London. The lamp is shown in the illustration herewith, and is provided with a 4-volt accumulator in a celluloid case of the non-spilling type. Its storage capacity gives a good light for about 10 hours.

ONEWATT LAMP.—Messrs. Siemens Bros. Dynamo Works have ready a leaflet dealing with their new "Onewatt" lamp, which contains, on what may be called the obverse side, an illustration of the lamp, and details of its efficiencies and dimensions and price. On the reverse side are set out in prominent form a number of the distinctive features of the lamp. These leaflets will be supplied to contractors overprinted with their own names on application.

LIGHT ACCESSORIES.—Messrs. D. H. Bonnella & Son, of Mortimer-street, London, W., have issued a section of their catalogue dealing more especially with wall and floor sockets and pressel switches. These various lines are illustrated and seem to be all that can be desired from the point of view of sturdiness of the work they are designed to carry out.

BANKRUPTCIES, LIQUIDATIONS, &c.

The public examination of Alfred Ernest Felgate and Wm. Storey, electrical engineers, 10, Queen Victoria-street, Reading, took place last week.

Gross liabilities were returned at £3,012. 8s. 3d., of which £2,412. 2s. 9d. was expected to rank; and assets estimated to produce £863. 7s. 9d., leaving a deficiency of £1,753. 15s. The Official Receiver questioned Felgate as to the causes of his failure, and he admitted that, considering he had been carrying on business with borrowed money, he had not been solvent practically from the start. Trade had been bad in Reading during the last few years, and there was a heavy loss on realisation of stock. Examination was adjourned.

Wm. H. Palmer, electrician, 10, Gt. Castle-street (lately trading at 7, Gt. Castle-street), Oxford-street, London, W., has been adjudicated bankrupt.

The public examination of Hy. K. P. Barham (trading as the South of England Electrical Engineering Co.), 60, Fratton-road, Portsmouth, will take place on April 25 at the Court House, St. Thomas-street, Portsmouth.

Claims against the Contraflo Condenser Co. (Ltd.) and the Contraflo Continental Patents Co. (Ltd.), whose undertakings are to be transferred to the Contraflo Condenser & Kinetic Air Pump Co.

Digitized by Google

(Ltd.), by May 7 to Mr. W. S. Gregg, 3 and 5, Crown-court, Old Broad-street, London, E.C., at which address meetings of creditors will be held on April 21.

A meeting to receive an account of the winding-up of Amalgamated Dry Batteries (Ltd.) will be held on May 26 at 394, Moorgate Station-chambers, London, E.C.

A meeting to receive an account of the winding-up of the City of Wellington Electric Light & Power Co. (Ltd.) will be held on May 23 at 180, Dashwood House, New Broad-street, London, E.C.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

February 7, 1910.

2,981 ADAMS MFG. CO. (Cutler Hammer Mfg. Co., U.S.) Electric switches.*
2,983 WESTINGHOUSE METALLFADEN GLUHLAMPENFABRIK G.M.B.H. Decarbonising metallic filaments for incandescent electric lamps. (Date applied for, 19/2/09.)*†
3,007 SUCKLING. Shade carriers for electric lamp-holders.
3,011 B.T.-H. CO. (G.E. Co., U.S.) Electric braking.
3,012 PHŒNIX DYNAMO MFG. CO. & POHL. Dynamo-electric machines.
3,013 WINSBOROUGH. Safety apparatus for use with electrical installations.
3,015 DANIEL. Arc lamp.*
3,019 LAMKIN & HUNTER. Electric telegraphy.

February 8, 1910.

3,052 BUCKLEY. Cleaning and disinfecting telephone receivers.
3,068 POOLEY. Motor-starting switches.
3,098 CHILDS & HILL. Electric controllers.
3,114 B.T.-H. CO. (G.E. Co., U.S.) Alternating-current motors of the commutator type.
3,117 SIEMENS-SCHUCKERTWERKE G.M.B.H. Transmitting power by means of polyphase alternating electric currents. (Date applied for, 27/2/09.)*†
3,118 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges., Germany.) Telephone exchanges.*

February 9, 1910.

3,125 PARSONS. Driving gear for ignition magnetos and similar devices.
3,137 RIDER. Mechanical ears, crossings, switches, frogs and section insulators for supporting the overhead wires for electric tramways.
3,153 KIDD. Morse signalling apparatus.
3,160 CHURTON & SMITH. Alternating-current induction motors.
3,163 ABBOTT. Cooking and the like by electricity or otherwise.
3,174 HOOKHAM. Electricity motor meters.
3,185 JOEL. Portable electric lamps.
3,186 QUAIN, TRUE & WADE-BROWNE. Electric lamps.
3,199 COMPAGNIE DE SIGNAUX ELECTRIQUES POUR CHEMINS DE FER. Controlling railway points and signals. (Date applied for, 11/2/09.)*†
3,208 CADDY. Flexible electric wires or cables.
3,209 BIGGE & BUTT. Induction coils and transformer apparatus.

February 10, 1910.

3,250 SPRAGUE & CHAMBERLAIN & HOOKHAM. Prepayment electricity meters.*
3,260 ELLIS. Expansion device for a gasolier, electrolier or the like.
3,294 HANDCOCK & DYKES. Electric meter systems.
3,307 DREIER. Electric chisels.
3,310 ETABLISSEMENTS DE DION BOUTON (SOC. ANON.). Electric ignition devices for internal combustion engines. (Date applied for, 11/2/09.)*†
3,314 STACHOW. Magnetic ore separators. (Date applied for, 19/2/09.)*†
3,318 HAWKER & MARKT. Electric switch for electric lamp-holders, wall switches and the like.
3,328 LEITNER. Induction spark arrester for direct-current apparatus.
3,329 ADAM. Protecting electric conductors.
3,336 B.T.-H. CO. (G.E. Co., U.S.) Brushes for dynamo-electric machines.
3,340 HEALING & CO. (Juzo Kajiura, Japan.) Electric telegraphy.

February 11, 1910.

3,380 PAPE. Grid for electric storage batteries.
3,381 PAPE. Storage batteries.
3,383 WINTERS. Combined trolley-wire hangers and automatic circuit-breakers.*
3,400 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges., Germany.) Telephone exchanges.*
3,410 MURPHY. Electric valves. (Date applied for, 19/8/09. Comprised in application No. 19,090, dated 19/8/09.)*
3,411 PERRY & BROWN. Systems for telegraphy and telephony.
3,421 SOCIETE ANONYME ELECTRO-METALLURGIQUE (PROCEDES PAUL GIROD). Supplying electric furnaces with polyphase currents. (Date applied for, 26/8/09.)*†
3,435 LEITNER. Electric lighting of trains.

February 12, 1910.

3,462 STOTHERT & PITT & PITT. Cranes and winches operated by electric motors.
3,475 SMITH. Portable electric lamps.
3,518 ASHTON. Reduction of voltage at terminals of electric lamps working on alternate-current circuits.

SPECIFICATIONS PUBLISHED.

1909 SPECIFICATIONS.

2,285 MASCORD, LANGE & CHITTY. Motors and transmission gear.
2,311 DAWBARN. Contact-making devices.
2,383 READ. Starting and controlling electric motors.
2,520 HEYLAND. Regulating system for alternate-current installations. (Date applied for, 3/2/08.)
2,715 BAERLOCKER. Controllers for electric motors.
2,749 GARDE & ADAMS. Electrodes of scondary batteries (accumulators). (Date applied for, 2/4/08.)
2,754 RORKE & RORKE. Switches for electrical purposes.
2,755 SCHULZ. Unipolar turbo-dynamo with the blade wheels running in opposite directions.
2,779 JOHNSTONE. Plug fuses and fuse boxes.
2,943 THOMAS. Electrical controllers.
3,046 PECK, FAYE-HANSEN & LUSTGARTEN. Alternating electric current distribution systems.
3,105 SIMPLEX CONDUITS & ELLIOTT. Switches and adapters for controlling lamps.
3,176 DANNATT. Electric switches, electricity meters and similar apparatus. (Cognate application, 18,268/09.)
3,191 CURTIS & ADAMS MFG. CO. Electrical resistances.
3,192 B.T.-H. CO. & WEDMORE. Protective devices for power transmission systems.
3,371 HOLMAN. Arc lamps. (Addition to No. 27,536/08.)
3,533 PECK. Control systems for electric motors.
3,554 FENNELL & PERRY. Electric radiators and other apparatus.

COMPANIES' MEETINGS AND REPORTS.

AIRDRIE & COATBRIDGE TRAMWAYS CO.—The capital expended during 1909 was £104.7s. 1d., making the total expenditure £67,304.16s.4d. The revenue for the year amounted to £11,666. 0s. 2d. compared with £11,808. 8s. 2d. for 1908. After deducting all expenses (including repairs and maintenance, interest and provision for permanent way renewals) the profit was £1,700. 10s. 1d., which, added to £282. 17s. 1d. brought forward, makes £1,983. 7s. 2d. £200 has been placed to sinking fund for loan redemption and £250 to depreciation reserve. A dividend at the rate of 3 per cent. per annum on the ordinary shares (£1,350) is recommended, leaving £183. 7s. 2d. to be carried forward.

ARBROATH ELECTRIC LIGHT & POWER CO. (LTD.)—At the meeting on Tuesday the Chairman, Mr. G. Balfour, stated, in the moving the adoption of the annual report, that there had been a satisfactory increase in the business of the company during the past year, and that it was advisable to extend the plant at the power station. The net profit was £426. 16s. 6d., and a total of £503. 9s. 6d. was being carried forward.

BELL'S ASBESTOS CO. (LTD.)—The directors' report for 1909 states that the net profit was £13,902, and with amount forward (£15,266) made £29,168. The absorption of the United Asbestos Co. has been effected. A dividend is recommended of 1s. 6d. per share (tax free) (making 12½ per cent. for the year), carrying forward £14,168.

CUBA SUBMARINE TELEGRAPH CO. (LTD.)—The report of the directors for the half-year ended Dec. 31 last shows that the total receipts of the six months were £16,376. 15s. 3d. and expenses £6,415. 1s. 7d., leaving a balance of £9,961. 13s. 8d., to which has to be added £7,059. 5s. 5d. brought forward, making £17,020. 19s. 1d. £2,000 has been added to reserve, which now stands at £116,000. The preference dividend absorbs £3,000, leaving £12,020. 19s. 1d., and the directors recommend payment of a dividend at the rate of 6 per cent. on the ordinary shares, tax free. £7,220. 19s. 1d. is carried forward. The company's cables continue in good working order.

CRAIGPARK ELECTRIC CABLE CO. (LTD.)—The nett profit for the year ended March 31 was £6,243. 14s., which, with £477. 6s. 2d. brought forward, makes £6,721. 0s. 2d. The directors recommend that £500 be applied towards depreciation of buildings and machinery, that £500 be placed to reserve and that dividends of 6 per cent. per annum be paid on the preference and ordinary shares, leaving £1,221. 0s. 2d. to be carried forward. During the year the company's business has continued to extend. The result, however, has not been so satisfactory as could be desired, and is entirely due to the great increase in the price of raw rubber. The directors have appointed Mr. Peter Rintoul, C.A., to the vacancy on the board caused by the death of Mr. W. R. Dick.

DEUTSCH-ATLANTISCHE TELEGRAPHENGESELLSCHAFT (COLOGNE)—The report of the directors of this company for the year ended December, 1909, states that the receipts from the Atlantic and the Vigo cables exceeded those of 1908. The Norddeutsche Seekabelwerke A.G. (Nordenham) have been engaged upon the laying of the first portion of the cable to South America, and will probably be fully employed during 1910. The net profit was M.2,520,890 (£126,045), compared with M.2,154,407 (£107,720) in the previous year. M.126,044 (£6,302) has been placed to reserve and M.500,000 (£25,000) to special reserve and repairs funds; dividend of 7 per cent. (as in 1908) requires M.1,680,000 (£84,000) and M.475,549 (£23,777) is carried forward, compared with £22,271 last year.

ISLE OF WIGHT ELECTRIC LIGHT & POWER CO. (LTD.)—At the recent meeting of this company the chairman (Mr. F. E. Gripper) stated that they had added the equivalent of 4,000 8 c.p. lamps to their system, and the revenue had increased by £450. The year's trading showed an increased profit of £145.

LA PLATA ELECTRIC TRAMWAYS CO. (LTD.)—At the meeting on Tuesday the chairman (Mr. W. Hamilton) said the electrification of the first section of the tramways, comprising over 3 miles of single track, was opened for traffic at the beginning of January, and a second section (comprising 5 miles of single track) was opened on 3rd inst. Those two sections included most of the principal lines of the city. The results of working by electricity were satisfactory.

LISBON ELECTRIC TRAMWAYS (LTD.)—The result of the operations for the past year, after deducting interest, London office expenses, &c., shows a net profit of £103,766. 1s. 9d., added to £3,380. 4s. 2d. brought forward, making £107,146. 5s. 11d. £35,000 has been placed to depreciation reserve, £5,000 to credit of exchange reserve, and £5,000 as a nucleus for the future establishment of an employés pension fund. Investments have been written down to market value. After providing for these charges the available balance is £62,146. 5s. 11d., and preference dividend (£25,533. 3s. 8d.) has been paid. An interim dividend of 2½ per cent. has been paid on the ordinary shares (£15,850. 13s.) and payment of a final dividend of 3 per cent. (£19,020. 15s. 7d.) is now recommended, making 5½ per cent. for 1909. The balance (£1,741. 13s. 8d.) is carried forward. Traffics continue satisfactory, and show a steady increase over 1908.

LONDON UNITED TRAMWAYS (LTD.)—For the year ended Dec. 31, last the gross receipts were £318,226. 6s. 3d., and working and general expenses, maintenance and repairs £226,566. 15s. 8d., leaving, with balance forward, net revenue £91,986. 8s. 3d. After payment of interest, &c., there remains £21,950. 5s. 7d. £21,000 is put to reserve for renewals

Digitized by Google

and £950. 5s. 7d. carried forward. Gross receipts show a decrease of £30,163. 18s. 7d. and working expenses an increase of £6,334. 11s. 6d. compared with 1908. The directors have carefully considered the condition of the permanent way and rolling stock, and they deem it advisable, from the standpoints of both economy and efficiency, that certain repairs which have become necessary should be undertaken immediately. They therefore propose to forego payment of any preference dividend for the past year, and to utilise the reserve funds for these repairs. The directors have deposited a bill to extend the period for the reconstruction for electric traction of the tramway along the Kew-road, Richmond. Sir Clifton Robinson having resigned the position of managing director and engineer, Mr. A. H. Stanley has been appointed to succeed him as managing director and Mr. Jas. R. Chapman, having returned to the United States, has resigned his seat on the board.

METROPOLITAN ELECTRIC TRAMWAYS (LTD.)—At the meeting last week the chairman (Mr. E. Garcke) said the tribulations of most tramway companies in this country were so great and so well known that the shareholders of the company had some difficulty in believing that their position was satisfactory, that the prospects were good, and that the payment of a dividend at the rate of 5 per cent. on the ordinary shares was compatible with the maintenance of the property and the adequate provision for depreciation. Nevertheless, such were the facts. The primary reason of that contentment and the absence of anxiety was undoubtedly the arrangement which they were able to make with the local authorities. This enabled them to maintain a contented and efficient staff of officials who were able to devote the whole of their energies to the development of the business. With the extensions opened during the past year they had practically completed that important system of tramways and light railways in the North Metropolitan area. Their network was fed and tapped by no less than five terminal stations of tube railways. That would at once indicate the enormous scope there was for the development of tramways in the area. Those tube railways were a great advantage to them, but he was quite justified in saying that the advantage to the tubes was also great. They had powers for a small tramway at Watford, which was still under consideration, and there were one or two small lines to be completed. There was a small connecting tramway line from Enfield to Ponder's End, and a small extension at Harrow-road. With those exceptions, the system was practically complete, and they might, at any rate for the immediate future, consider the capital account of the company as closed. With regard to the North Metropolitan Power Co., the increase in power consumers was quite satisfactory, amounting to something like 70 per cent. in the past year, and as the districts developed by means of the travelling facilities now completed, and the general favourable situation of the area in regard to manufacturers, &c., he had no doubt that the business of the Power Company would steadily increase. The dividend on their shares in that company this year was 6 per cent., against 5 per cent. in the preceding year. They were now free to devote their energies to the development of the Power Company, which was capable of very considerable extension, and upon the working up of their traffic on the tramways and light railways.

ORIENTAL TELEPHONE & ELECTRIC CO. (LTD.)—Including £5,263. 4s brought forward, deducting the interim dividends of 3 per cent. on both the preference and ordinary shares, and making provision for redemption of debenture stock, and other charges, the amount to be dealt with for the year to Dec. 31 is £28,994. 5s. The directors recommend payment of the final preference dividend (£1,500) and a final dividend of 5 per cent., tax free, on the ordinary shares (making 8 per cent. for the year) (£8,965. 13s.), the transfer to reserve of £7,500 and of £500 for contemplated pension scheme, leaving £10,528. 12s. to be carried forward. The exchanges worked by the company continue to show improving revenues. In Mauritius negotiations are still proceeding with the Government with a view to enlarge the field of operations. The Indian local companies report a continued accession of subscribers. The Bengal Telephone Co. has declared the same dividend as for 1908 (5 per cent.) and the Bombay Telephone Co. 7 per cent. (against 6 per cent. for 1908). The Telephone Co. of Egypt has also shown further increases of business during 1909, and has again declared a dividend of 10 per cent. for the year on both preferred and deferred shares. The China & Japan Telephone & Electric Co. also made good progress, and dividends of 5 per cent. for 1908 and 1909 have been declared.

ROTHESAY TRAMWAYS CO. (LTD.)—The total revenue for 1909 was £10,565. 16s. compared with £10,431. 17s. 2d. for 1908. The working expenses (£5,689. 16s. 7d.) showed a decrease of £297. 18s. 8d. After deducting expenses and providing £400 for renewals, the balance is £1,306. 18s. 4d. making, with £82. 10s. 5d. brought forward, £1,389. 8s. 9d. The directors recommend that £400 be applied to sinking fund for loan redemption, and £100 to depreciation and reserve, and that a dividend at the rate of 1 per cent. on the ordinary shares (£638. 15s.) be paid, leaving £250. 13s. 9d. to be carried forward.

SOUTHPORT TRAMWAYS CO. (LTD.)—At the meeting on Monday the directors' report stated that the decrease in traffic receipts was mainly due to unfavourable weather and trade depression, but the competition of the electrified section of the Lancashire & Yorkshire Railway and of the Southport Corporation tramways had not been without its effect on the receipts. After paying £5,573. 8s. 4d. to the local authorities under various agreements and other sums, the accounts showed a debit balance of £818. 14s., which, reduced by £126. 18s. 8d. brought forward, left a debit balance of £691. 15s. 4d.

NEW COMPANIES.

BRITISH ALUMINIUM CO. (LTD.) (108,758)—Reg. April 12, capital £1,000,000 in £1 shares (300,000 preferred), to acquire any minerals, claysor other substances suitable for the production or manufacture of aluminium, sodium, iron or other metals, to carry on the business of miners, manufacturers of and dealers in aluminium and its alloys, &c., to acquire and deal in any manner with all or part of the undertaking and assets of the Loch Leven Water & Electric Power Co., and to adopt an agreement with the British Aluminium Co. (Ltd.) (in liquidation).

BRITISH ARC WELDING CO. (LTD.) (108,759)—Reg. April 11, capital £15,000 in £10 shares, to carry on the business of welders, electrical, civil and mechanical engineers, electricians, &c. Private company. First directors, R. S. Kennedy and J. Kennedy. Reg. office, Suffolk House, Laurence Pountney-hill, London, E.C.

ELECTRICAL TRUST (LTD.) (108,846)—Reg. April 14, capital £2,500 in 2,000 ordinary shares of £1 each and 10,000 founders' shares of 1s. each, to carry on the business of electrical, telegraph, telephone and mechanical engineers, cable makers, dealers in electrical and other motors, generators and accumulators, &c. Private company. First directors, J. Metcalfe and A. C. Vincent. Reg. office, 9 & 10, Pancras-lane, London, E.C.

HILL, HARDING & CO. (LTD.)—Reg. April 16, capital £1,000 in 950 preferred ordinary shares of £1 each and 1,000 deferred shares of 1s. each, to carry on the business of electrical and surgical instrument manufacturers carried on as Hills, Harding & Co., together with a certain invention for an improved device for controlling an auxiliary electric circuit requiring a voltage which is lower than that of the source of electrical supply. Private company. First directors, H. W. Hill (life director), H. W. Chapman and W. G. Harding. Reg. office, Shandon-road, London, S.W.

NU-ADS (LTD.) (108,858)—Reg. April 14, capital £2,000 in £1 shares, to take over certain patent rights from F. J. Blaxley, C. C. Chapman, A. C. Harris and F. H. Blaxley, to carry on the business of manufacturers of and dealers in electric advertising signs, &c. Private company. First directors, F. J. Blaxley (managing director) and A. C. Harris.

RAILOPHONES (LTD.) (103,940)—Reg. April 16, capital £500 in £1 shares, to carry on the business of electricians, telegraph and telephone instrument makers, engineers, wire drawers, &c. Private company. Reg. office, 21, Wood End-road, Erdington, Warwick.

A. WARD & CO. (LTD.) (108,793)—Reg. April 13, capital £3,000 in £1 shares, to carry on the business of electrical, automobile, mechanical and general engineers, founders, boiler makers, &c. Private company. First directors, A. V. Ward and G. L. Kirkpatrick. Reg. office, 85, Shaftesbury-avenue, London, W.

CITY NOTES.

MEMORANDA (April 21).—**Bank rate 4 per cent.** (since March 17, 1910). **Price of silver,** 24⅛d. per oz. Consols 80¾—81⅛ for money and 81—81¼ for account. Consols Pay Day, May 5; Stock and Shares Continuation Days, April 27 and May 10; Ticket Days, April 28 and May 11; Pay Days, April 29 and May 12; Mining Shares Carry Over Day, April 26.

PRICES OF METALS (London).—*Copper*, cash, 55⅛; three months, 57⅛. *Lead*, English, 12⅞—13¼; foreign, cash, 12⅜; three months, 12⅝. *Spelter*, foreign, 22⅜. *Tin*, English, 149—151; foreign, cash, 150¼; three months, 151¾. *Iron*, Cleveland, cash, 50/7, and three months, 51/7.

BRITISH COLUMBIA ELECTRIC RAILWAY CO. (LTD.)—An interim dividend at the rate of 8 per cent. has been declared on the deferred ordinary stock for the half-year to Dec. 31 last.

COUNTY OF LONDON ELECTRIC SUPPLY CO. (LTD).—The transfer books and register of holders of the second debenture stock are closed from 18th to 30th inst., inclusive, preparatory to payment of interest due May 1.

COVENTRY ELECTRIC TRAMWAYS (LTD.)—Gross receipts during the past year were £28,350, expenses £18,729 and net earnings £9,621. Net profit was £6,939. The directors recommend a dividend of 3½ per cent.

EASTERN TELEGRAPH CO. (LTD.)—The company announce payment by warrants on May 2 of interest for the half-year ending 30th inst. on their 4 per cent. mortgage debenture stock. The transfer books of the debenture stock will be closed from 27th to 30th inst. inclusive.

EASTERN & SOUTH AFRICAN TELEGRAPH CO. (LTD.)—This company announce payment by warrants on May 2 of interest for the half-year ending April 30 on their 4 per cent. Mauritius subsidy debentures. The transfer books will be closed from 27th to 30th inst. inclusive.

MONTE VIDEO TELEPHONE CO. (LTD.)—The directors have declared an interim dividend for the half-year ended Jan. 31 at the rate of 6 per cent. per annum on the ordinary shares.

MONTREAL LIGHT, HEAT & POWER CO.—A dividend of 1¾ per cent. for the quarter ended April 30 has been declared.

STOCK EXCHANGE NOTICE.—The Stock Exchange committee have granted a quotation to a further issue of £350,000 5 per cent. 50 year mortgage bonds of the *Rio de Janeiro Tramway, Light & Power Co.* (*Ltd.*)

NOTES.

The Institution of Electrical Engineers.

AT the meeting of the Institution last week, when the nominations were announced for the new Council, some surprise was caused by Mr. W. A. CHAMEN proposing (in accordance with the Articles of Association) Mr. H. FARADAY PROCTOR as a further nomination. This proposal was seconded by Mr. W. W. LACKIE, and supported by Messrs. H. COLLINGS BISHOP, A. ELLIS, H. D. MUNRO, E. G. OKELL, H. T. SULLY, C. A. L. PRUSMANN, W. J. BACHE, R. A. CHATTOCK, T. O. CALLENDER, D. E. ROBERTS, T. SCHONTHEIL, and A. J. HODGSON. Mr. CHAMEN, in putting forward the nomination, remarked that he did not do so in any antagonistic spirit. This we can quite believe, as we think it may very well be said that the nominations this year are more acceptable to the general body of members than has often been the case. It is really just as well that the innovation of outside nominations should come when there is not any marked dissatisfaction. Undoubtedly, the present practice is not satisfactory, as nominations by the Council alone are always liable to lead to undesirable results for very obvious reasons. We hope, therefore, that nominations will come in future from the general body of members as a matter of course, and we are glad to see that the President welcomed Mr. CHAMEN'S action. The only objection that we can see is that members may possibly be disinclined to have their names put down for a ballot which may lead to their rejection, as such must inevitably be the fate of some of the candidates if more are nominated than there are vacancies to be filled.

The Westminster Street Lighting Contracts.

IN our last issue we commented upon the Westminster street lighting contract, and referred to Mr. JACQUES ABADY, the chairman of the Works Committee, as an "out-and-out supporter of gas." We are glad to find that in this statement we were mistaken, and that Mr. ABADY is equally well disposed to electric lighting as to gas lighting so long as it is a case of equal light for the same money. It is highly important that a chairman should be impartial in such matters, for municipal government has often suffered seriously by the neglect of the simple principle that the ratepayers' pocket and interests are what should be kept in view before anything else. We also referred to Mr. ABADY'S views as being "somewhat biased." We came to this conclusion because, in the account of the proceedings, he seemed to lack sympathy with the deputation of shopkeepers who desired electric light to be retained in Regent-street and the decision of the Council to be postponed for further consideration. It appears, however, that there were objections (which were not apparent in his remarks) to the adoption of such a course, and had we been aware of these the expression would not have been used. The essential fact remains that the price quoted by the gas company was much lower than that by the electric light companies for the same light units, and so long as that is the case, and the guarantees are considered satisfactory, a Committee have very little option but to recommend acceptance of the lower tender. It is interesting, however, to enquire why there should be such a disparity in the prices tendered.

DURING the last week the situation has become more clear, as it has been possible to unravel to some extent the basis on which the tenders stand. This remark, however, does not apply to the gas tenders, for the Gas Light & Coke Co. are particularly reticent about the matter. Perhaps this attitude is only to be expected. We understand

Digitized by Google

however, that the Gas Company are about to use for the 90 c.p. units a new type of lamp with inverted mantle, the maintenance of which is expected to be much lower than that of the older form of lamp hitherto used. Even so it is pretty clear that the gas is being supplied at a price very much lower than is usually charged. The prices are said to be the result partly of the Gas Company's confidence in recent improvements and partly due to the necessity for regarding street lighting as an advertisement.

In regard to street lighting by electricity the present situation is so important that we offer no apology for dealing with it at some length. Taking into account the great disparity between the tenders of the competing illuminants the question arises whether the electricity supply companies could not have quoted lower prices. During the past week we have taken the opportunity of going into this matter, and through the kindness of the various engineers, we are now able to give, in some detail, the figures on which the contract prices were based. Before doing so, however, it may be as well to point out that the prices for maintenance given in Table III. of the article on p. 66 of our last issue include, in the case of the electricity supply companies, a proportion of the capital charges necessary in connection with the new work—*i.e.*, for laying the mains and services required. The outlay is, in some cases, very large, since some of the districts to be lighted, especially in the area of the Westminster Electric Supply Corpn., are only provided with mains to a small extent, and it would also have been necessary to lay special arc lamp services. For instance, in the case of one particular district in Westminster, in which electric light is fairly generally used, it may be mentioned that over £8,000 would have to be so expended, while in the Pimlico district, where electric lighting is not nearly so general, it would be nearer £18,000.

In turning to the actual cost to the electricity supply companies, it may be well to take as an example the district served by the St. James' & Pall Mall Electric Light Co. This includes not only the lighting of Regent-street, which has loomed large in the discussion on this question, but also a number of side streets where electric lighting is not at present employed to any great extent. Under the conditions of the contract the Company were not able to tender for only a part of the district, and therefore, while they could have maintained lamps in Regent-street itself at a comparatively low cost, this advantage was offset by the high capital expenditure necessary in the rest of the district, so that the average annual charge over the whole area for a 3,000 c.p. unit worked out at £28 on the five-year basis. This figure was arrived at as follows:—£7. 6s. per annum for carbons, £2. 10s. per annum for trimming, and £1. 14s. per annum for repairs. These are actual working costs and are higher than those commonly found in arc lighting, because not only is the required candle-power high but there is a considerable margin, a figure of 3,575 c.p. being obtained on the photometer at ground level. To these costs had to be added that of the current, and a figure on account of the capital expenditure necessary to instal the new system. It was decided to supply energy at ¾d. per unit, but to include the capital charges in the energy charge, which then worked out at 1½d. per unit on the five years, 1¼d. on the 10 years, and 1d. on the 15 years' contract. It will thus be seen that an attempt was made to pay off such capital expenditure as could be charged against the arc lighting within the term of the contract. In the case of the incandescent lighting the same policy was followed, and as the capital charges for mains are, in this case, large compared with the cost of energy, the price per lamp per annum becomes what seems, at first sight, unduly high. On a 15 years' contract the price is naturally much lower than on a 5 years' contract, because the capital charges are spread over a longer period.

From the result of the tenders it is quite apparent that the electricity companies must reduce their costs if they desire to obtain street lighting under the present conditions of competition in London. It will be admitted that the price included for energy was not high, but whether capital charges should be included on the basis considered above is a question that is open to some doubt. We are inclined to think such a policy is not expedient, and that the companies must take the same risks in street lighting as with private consumers, unless they are prepared to drop the former. Tendering was, no doubt, rendered difficult by the fact that in some areas there are mains already in existence, whilst in others there are none. Obviously the price desired would vary with the locality, but an average price has been given to cover the possibility of lamps being required where there are at present no mains. Thus it happens that the price for arc lighting in Regent-street would be raised by the new tenders above the price at present paid. This seems illogical, or at least very undesirable. It is important that the electricity companies should retain the street lighting they at present have, and with this object in view it would seem better to have quoted prices at least not higher than those hitherto obtained, and preferably lower. This course would certainly have involved a risk as to capital charges, but if necessary we think that this risk should be met by co-operation as mentioned in our last issue. The question should be viewed as a whole, and the damaging effect of the return of such thoroughfares as Regent-street to gas lighting must be borne in mind. We repeat that it is a question of advertisement, and as such it may be worth while to adopt a broad policy and even to supply at some loss. We also think that the specification might very well have been drawn so as to allow separate prices to be tendered for the continuance of existing lighting. The letter of the St. James' & Pall Mall Electric Light Co. in another column is of interest and serves to emphasise this point very clearly.

Tramway Reserve Funds.

To have to report decreased revenue is at all times a thankless task for a chairman of any business concern, but when such decrease takes place in spite of the growth of an undertaking, the task becomes increasingly unpleasant. This is, however, the unfortunate position of the London

Digitized by Google

United Tramways. In 1906 there were 45 miles of route in operation and the traffic brought in £325,000, whilst, in 1909, with 55¼ miles of route, the revenue only amounted to £317,000, a decrease of £29,000 on that of the previous year. For this unsatisfactory progress, or, to be more correct, lack of progress, two reasons were assigned by the Chairman at the meeting last week—namely, the unfavourable weather (from the traffic point of view) during the past three years, and the competition of railways and omnibuses. During recent years there have undoubtedly been extensive changes in the means of locomotion in the London area, and as the effects could scarcely have been foreseen a few years ago, it is not surprising that the estimates of the directors of the London United Tramways as to the expansion of the undertaking have not been realised. To increase the troubles of the Company the question of renewals is now becoming increasingly important; in fact, it has been found necessary on the present occasion to pass over the dividend on the preference shares and to devote the whole of the profits to the maintenance of the undertaking. The rapid increase in the cost of maintaining the track and equipment, with the possibility of a decline in the revenue due to extraneous causes, render it most important that an adequate reserve fund should be provided in the early days of a tramway undertaking without postponing such steps until the undertaking shall have developed.

In this connection it may be mentioned that the reserve fund of the London County Council tramways has also been brought into prominence during the last few days by the estimates of the Finance Committee of the Council for the current year. These were presented at the meeting of the Council on Tuesday last, when Mr. Hayes Fisher, Chairman of the Finance Committee, announced that a surplus, estimated at £244,132, would be shown by the Council's tramway undertaking on the present year's working. It is proposed to allocate the whole of this sum to the renewals and general reserve funds, which on this basis will together amount by March, 1911, to about £700,000. It is interesting to notice that Mr. Fisher advised the Council to dismiss for the present from their calculations any suggestion of relieving the rates by means of profits obtained from the tramway undertaking. In so doing, however, he did not wish to give the impression that the tramway undertaking was not in a flourishing condition; in fact, he believed its financial position was very satisfactory. In view of the developments which have taken place in the London traffic problem during recent years and the vicissitudes of tramways and other forms of locomotion, we think the Council will be well advised to follow the Financial Committee's recommendation as regards the provision of an adequate reserve fund.

Cable Interruptions.

International Conference of Government Telegraph and Telephone Engineers.—The first conference was held at Budapest in September, 1908, and in The Electrician for February 25th last we gave particulars relating to the next Conference, with a list of the subjects to be discussed. We now learn that the coming Conference will be held from 4th to 11th September inclusive. The French Administration is disposed to hold from 4th to 18th September, in Paris (if a sufficient number of exhibits are entered), a public exhibition of existing automatic telephone systems. It is considered that this exhibition will greatly facilitate the study of one of the principal questions submitted to the Conference. The Administration will, if the suggestion is carried through, provide free space and lighting and will be responsible for the safety of the exhibits, which should include apparatus for at least 100 subscribers and should, as far as possible, represent inter-communication stations. Particulars as to space required must be sent as soon as possible, but not later than May 20th, to M. le Ministre des Travaux Publics des Postes et des Télégraphes de France (Direction de l'Exploitation Téléphonique, 103, rue de Grenelle, Paris).

Systems of Charging for Electric Light.—We have received from Mr. A. H. Seabrook a copy of a pamphlet with this title, which has been issued by the St. Marylebone electricity department for the benefit of consumers and prospective consumers of electrical energy in the borough. The pamphlet contains a brief explanation, in as non-technical language as possible, of the "maximum-demand" and "telephone" systems of charging. After describing the principle of the maximum-demand indicator and the basis on which the consumer's bill is made out on this system, it is shown how much simpler is the "telephone" system of charging, all that is necessary being that the consumer must fill up a form (or let the electricity department's representative do this) stating the particulars of the lamps installed. From the number and candle-power of these lamps the annual fixed charge is determined, and for all energy consumed a further charge of 1d. per unit is made. In addition to simplicity, other advantages of this system are: (1) The consumer knows within about 10 per cent. what his annual bill will be; (2) no special wiring or meter is necessary if electrical apparatus such as irons, kettles, stoves, fans, &c., are installed. It should be noted that a small annual charge is made for each piece of apparatus installed; thus, for an electric iron the annual charge (payable in advance) is 5s., whilst for a four-lamp radiator the consumer would be required to pay £1, the energy consumed, of course, passing through the lighting meter and being paid for at 1d. per unit. An annual sum of £2. 2s., however, allows a consumer to instal as much heating and other electrical apparatus (apart, of course, from lighting) as he wishes. It should be noted that the "telephone" system can only be applied to premises where electricity is used throughout for lighting purposes. It is, however, a distinct advance in methods of charging, and should do much to popularise still further the use of electric lighting and all forms of electrical apparatus. The fact that £7,000 has been received in St. Marylebone in annual charges payable in advance since this system came into use is an excellent testimonial to its value. Systems of charging, especially the maximum-demand system, are a stumbling block to the lay mind, and we do not doubt that this pamphlet will do something to clear up such difficulties.

Grants to University Colleges.—There was issued last week the report of the Advisory Committee who have been considering the disposal of the unallocated balance of the Treasury grant for 1909-10, after payment of the general grants to recognised colleges. With a view to the approaching reallocation of grants for the quinquennium beginning with the financial year 1910-11, the Committee have had under consideration the question whether any new colleges should be added to the list of those which participate in the Treasury grants. The following colleges have therefore been inspected: Royal Albert Memorial College (Exeter), East London College,

Digitized by Google

Birkbeck College and Hartley College (Southampton), the last-mentioned college being in receipt of a temporary grant.

The Committee first draw attention to some general considerations. They state that "Besides some institutions in London, there are several in various provincial centres of population which offer facilities for study and instruction of a university standard, both in pure science and in literary subjects, and that students attending them do, as a matter of fact, obtain the instruction they require in preparation for intermediate and final university examinations. Some of these institutions are in more or less intimate connection with the local university; others at present depend upon the external examinations of the University of London. These institutions do not in all respects satisfy the conditions which have been laid down as required to justify inclusion in the list for university college grants, but they are practically local colleges, performing a useful function as centres of literary culture as well as of technical or professional education. They deserve direct encouragement in this work, but it would be a misfortune to offer that encouragement in a way or on grounds which would tend to lead them out of their proper line of development as local colleges under distinctly municipal management. Such a policy, if carried out in advance of any real demand, is likely, instead of raising the general standard of the institutions as a whole and widening the range of learning and intellectual interest in the centres which they serve, to result in the provision of inferior university courses—inferior, that is, to those which exist in an institution where experience has shown that real university work can be carried on as the centre of intellectual life over a wide area. The growth of a true university institution is a slow business, is likely to be hindered rather than promoted by attempts at hasty development, and is certain to fail if such higher instruction as the neighbourhood is ready and anxious to receive is not made the basis of its development." On these considerations the Committee are unable to advise that the Hartley College, Southampton, should remain permanently on the list of university colleges in receipt of a Treasury grant. In order that the work of the college may not suffer during a transitional period they recommend that the grant, reduced to £1,500, be continued for the year ending March 31, 1911, but no longer. The Committee are also unable to recommend that the Royal Albert Memorial College, Exeter, and the Birkbeck College should be added to the list of university colleges receiving Treasury grants; but they recommend that the East London College should be awarded a grant, provided: (1) The college continue to be recognised as a school of the University of London; (2) that it be incorporated as a public educational institution; (3) that after such change by scheme in its standing and constitution as may be required, the resources of the college be sufficient for its support as a university college in accordance with the conditions prescribed by Section A of the Treasury Minute of June 3, 1909. The recommendations of the Committee have been approved.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. J. Rezelman contributes an article on "Leakage Reactance."

At the Institution of Electrical Engineers yesterday evening a Paper was read by Mr. W. W. Wood on "Earthed *versus* Insulated Neutral in Colliery Installations."

Last week the Friday evening discourse at the Royal Institution was delivered by Mr. T. Thorne-Baker, the subject being "The Telegraphy of Photographs, Wireless and by Wire."

Baku (Russia) municipality has recently raised a loan of 27 million roubles for electricity supply, electric tramways, &c.

It has been decided to convert the Northern Leopoldina (Brazil) Railway to electric traction.

The Southern Nigeria Railway Co. are about to raise a loan for an electric power station, for the construction of electric tramways at Dairen, &c.

Leicester Corporation have decided to put down additional generating plant at the tramways power station, at an estimated cost of £19,190.

London County Council recently communicated with Hackney Borough Council on the period of the loans sanctioned for the electricity undertaking, and suggested that instead of building up a large reserve fund it would be advisable to reduce the period of the current loans to periods equivalent to the terms now allowed by the County Council.

At the annual dinner of the Midland branch of the Electrical Contractors' Association last week the secretary, Mr. L. G. Tate, announced that his Association was in negotiation with the Association of Municipal Corporations to see if some understanding could be arrived at.

Hampstead (London) have decided to dispose of some of the existing plant at the electricity works and to obtain tenders for new plant at a total cost of about £18,000.

Legal.—The proceedings before Mr. Justice Parker, on a motion by the Corporation of London to prevent the County of London Electric Supply Co. from opening up London Bridge for the purpose of laying mains to link up the Company's southern and northern generating stations, were interesting from the fact that they show how London Bridge, although an important public thoroughfare, is held by the City Corporation to be outside any possible area of electricity supply at present constituted—that is to say, until certain very primitive formalities have been gone through, London Bridge can offer successful opposition to the connection of the north and south of London electrically.

INSTITUTIONS AND SOCIETIES.

Institution of Civil Engineers.—At the annual general meeting last Tuesday the result of the ballot for the election of officers was declared as follows: *President*, Mr. Alex. Siemens; *Vice-presidents*, Dr. W. C. Unwin and Messrs. R. Elliott-Cooper, A. G. Lyster and C. A. Brereton; *Members of Council*, Mr. J. A. F. Aspinall, Mr. B. H. Blyth, Mr. J. A. Brodie, Mr. W. B. Bryan, Col. R. E. B. Crompton, Mr. W. Davidson, Mr. E. B. Ellington, Mr. M. Fitzmaurice, Mr. J. P. Griffith, Sir A. Hadfield, Dr. C. A. Harrison, Mr. W. Hunter, Mr. G. R. Jebb, Mr. H. E. Jones, Sir W. T. Lewis, Mr. H. D. Lumsden, Sir T. Matthews, the Hon. C. A. Parsons, C.B., Mr. Alex. Ross, Mr. J. W. Shores, Mr. F. J. E. Spring, Mr. J. Strain, Sir F. R. Upcott, Sir P. Watts, Mr. W. B. Worthington and Mr. A. F. Yarrow.

It is announced that the 18th "James Forrest" Lecture will be delivered at The Institution on Wednesday, June 22nd, at 8 p.m., by Sir John Gavey, C.B., his subject being "Recent Developments of Telegraphy and Telephony."

Glasgow Section of the Institution of Electrical Engineers. At the meeting of this section, held on Tuesday, April 12th, the following nominations for the committee of the section for the session 1910-11 were made: *Chairman*, Mr. Sam Mavor; *Vice-Chairman*, Mr. J. A. Robertson; *Hon. Secretary and Treasurer*, Mr. J. E. Sayers; *Committee*, Messrs. W. McWhirter, T. B. Murray, T. C. Parsons and J. Ferguson.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, April 29th (to-day).

Students' Section of the Institution of Civil Engineers.

Visit to Southampton Docks, and to Messrs. Harland & Wolff's Engineering Shops.

TUESDAY, May 3rd.

Electro-Harmonic Society.

4:30 p.m. Annual General Meeting at the Institution of Electrical Engineers, 92, Victoria-street.

WEDNESDAY, May 4th.

Students' Section of the Institution of Electrical Engineers.

7:45 p.m. Annual General Meeting at 92, Victoria-street, S.W. The Paper announced to be read at this Meeting has been cancelled.

THURSDAY, May 5th.

Institution of Electrical Engineers.

8 p.m. Meeting at the Royal Society of Arts, John-street, Adelphi. Paper on "A Telephone Relay," by Mr. S. G. Brown.

Röntgen Society.

8:15 p.m. Meeting at 20, Hanover-square. Paper on "Quantitative Measurements of the Conversion of Cathode Rays into Röntgen Rays by Anticathodes of different Metals," by Mr. J. H. Gardiner.

IRON AND STEEL INSTITUTE.

Wednesday and Thursday, May 4th and 5th.

10 a.m. Meetings at the Institution of Civil Engineers, Great George-street. Among the Papers to be read are the following: "On the Girod Furnace and the Electric Smelting Works of the Paul Girod System," by Prof. W. Borchers; "On the Progress of Electric Smelting," by Mr. D. F. Campbell, and "On Developments in the Production of Electric Power; Its Application and Bearing upon the Iron and Steel Industries," by Mr. D. Selby Bigge.

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. B. Crompton, C.B.

The following orders have been issued for the current week:—

Monday, May 2nd, "A" Company.—Recruits Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 9:30 p.m.

Tuesday, May 3rd, "B" Company.—Company Drill, 7 to 9:30 p.m.

Wednesday, May 4th.—Gymnasium, 6 to 9:30 p.m.

Thursday, May 5th, "C" Company.—Recruits Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 8 p.m. Technical Drill, 8 to 9:30 p.m.

Friday, May 6th, "D" Company.—Company Drill, 7 to 8:30 p.m. Technical Drill, 8:45 to 9:45 p.m.

Saturday, May 7th, "D" Company.—Company Drill, 3:15 to 4:15 p.m.

EARTHED *VERSUS* INSULATED NEUTRALS IN COLLIERY INSTALLATIONS.*

BY W. WELLESLEY WOOD.

Summary.—The author discusses in detail the advantages and disadvantages of working in a three-phase colliery installation with an earthed as against an unearthed neutral. Although a hard and fast rule cannot be laid down, he concludes that generally an insulated neutral is better where permanent plant is at work and the cables are not liable to injury. Where portable machines are used or cables are liable to damage, automatic devices may be installed. A separate transformer with earthed neutral might be used to supply this plant.

A great deal of attention has recently been attracted to the question whether a three-phase colliery installation should work with an earthed or insulated neutral, and not only are there a number of supporters of both systems, but also a number of long-standing examples of each at work both on high and medium pressures, and with current taken in some cases from a supply company and in others from their own generating plant. Conditions vary so greatly in collieries and mines that what is suitable and perhaps necessary in one case may be absolutely dangerous in another. The principal advantages of each system are as follows:—

Earthed Neutral.—(1) Maximum potential to earth of any phase limited to 58 per cent. of line voltage. (2) Leakage to earth probably results in isolation of the damaged circuit. (3) Leakage tripping devices can be used which switch off the supply when an earth occurs on one phase, reducing danger of shock and explosion.

Insulated Neutral.—(1) Danger of shock and explosion is reduced, as contact with earth and one phase does not complete the circuit. (2) An earth on one phase does not cause an interruption of supply, for the same reason. (3) Stress on insulation under normal circumstances is less, and liability to flash to metallic casings considerably less. (4) Only two-trip coils instead of three are required to protect each circuit where an automatic switch is installed.

Power Taken from a Supply Company.—As the principal consideration is the safe operation of the underground plant, it is only proposed to consider briefly how the question affects generating machinery and transmission lines. Many collieries now take their power from a supply company, and where such an installation is connected without the intervention of a transformer, advantages (1) and (2) of the insulated system are minimised, as an earth on any part of the supply company's mains (possibly in another colliery) will have the same effect as an earth on the installation, but be beyond its control. Under such circumstances, and particularly where the voltage is high, say 5,000 or over, it is probably better to earth the neutral so that a faulty installation is isolated, and the stress to earth on healthy plants kept permanently at 58 per cent. of the line volts. In a high-tension installation the factor of safety of the installation is often small, and the sudden rise of pressure produced by an earth on one part of the system may damage the insulation of another part or cause a flash-over on motors. Where the supply is transformed the colliery circuit is a separately insulated one, and the above does not apply.

Generating Plant.—As far as the generating plant is concerned (where a colliery has its own supply) the earthing or insulating of the neutral makes very little difference, as although with alternators in parallel triple-frequency currents may give trouble with an earthed neutral, this can be got over by only earthing the neutral of one generator, or by the introduction of choking coils, and this point was discussed in Mr. Rider's Paper on the London County Council tramways. The conditions, moreover, under which most colliery stations work are less strenuous than in those of a supply company, where interruption of the service affects a large number of concerns, so that the earthing of one generator at a time would probably work satisfactorily.

Transmission Lines.—As far as transmission is concerned, the question of earthed *versus* insulated neutral is a very open one indeed, especially on voltages under 20,000, and the President of the High Tension Committee of the American Institute of Electrical Engineers, in opening the discussion on this subject, puts his conclusions as follows: "That some plants earthed the neutral, and its engineers considered it safe, and would never think of running in any other way, whilst the engineers of plants which did not earth the neutral would never think of doing such a thing."

Where the neutral is earthed, it has sometimes been found possible in emergencies to keep up the supply with two lines and an earth return, while with an insulated system the supply can be maintained with an earth on one phase, if the insulation of the system has a sufficient factor of safety to withstand the full-line voltage between any part of it and earth. These points are of more importance on a supply company's system than on the average colliery installation. Before considering the underground plant it is interesting to note that under certain conditions it is possible to get the full line voltage to earth in two phases of a system even with the neutral earthed on both high and low-tension sides of the transformers, if these are connected star to star, and the generator neutral is insulated. This is due to the instability of the neutral point under such conditions. Very often the first indication of anything wrong is the arcing of the lightning arresters.

Underground Plant.—The chief considerations in the underground plant are safety as regards shock and explosion, reliability and simplicity in working, and cost both of the installation and maintenance of the same.

Danger from Shock.—Although even on a perfectly insulated system of large size, or working at high pressure, it is possible to get a severe shock from the capacity effect alone, and without any actual circuit being completed, there is no doubt that on such a system there is less danger of fatal results from accidental contact with one live phase and earth, and particularly so on medium pressure installations. It must be noted, however, that very often on these medium-pressure systems the neutral point is connected to earth through the resistance of the leakage indicator. This resistance is generally designed to pass several hundred milliamperes, which is sufficient to give a fatal shock, and while it is, of course, much safer to get a shock in series with such a resistance which limits the current, this danger can be reduced by using the same electrostatic type of indicator usually supplied for higher voltages, or by the Nalder type of instrument which only passes a few milliamperes. Considered from this point of view there is no doubt that a system with earthed neutral presents greater dangers.

Limitation of Voltage.—With an earthed system the voltage between any point and earth cannot exceed 58 per cent. of the line pressure, but as fatal accidents have occurred with voltages as low as 150, this limiting of the voltage is not of any very great advantage, particularly in a colliery where the conditions are such as to make the men specially susceptible to the effects of electric shock.

Earthing of Metal Casings.—The best protection against the danger of shock from conducting bodies does not lie either in earthing or insulating the neutral, but in properly protecting or enclosing all live parts, and in efficiently earthing to the surrounding ground all motor frames, switch cases, &c. The earth wire should be large enough safely to carry the load which will blow the fuses of the plant it protects, and it should be frequently tested for continuity. In a dry pit it is often difficult to get a good earth connection, and to meet this difficulty some engineers carry either a separate cable or core for earthing purposes only, but this method may possibly be a source of danger unless the system is also earthed underground. For example, on a three-phase system with an earthed neutral, and an earth-plate at the generating supply end, a leak takes place near the motor on one of the outers. This motor is at work in a more or less insulating stratum, so that the resistance from the ground to the earth-plate at bank (except through the earth wire) is very high. The motor makes bad contact with the ground on which it stands, and there is a very considerable difference of potential between this ground and the motor. Anyone standing on this ground and touching the motor-case will get a possibly fatal shock. If the neutral is insulated it is necessary to have a leak on one of the other phases at bank before the same conditions can apply. It may be thought that this is a rather exaggerated case, but a non-fatal shock on somewhat the same principle as outlined above, and due to variations in the resistance of the strata, occurred recently in a colliery in Scotland, and on measuring the resistance between an earth-plate at bank and an earth connection at the bottom of the shaft, this was found to be 300,000 ohms. With regard to this question of earthing, Messrs. J. G. and R. G. Cunliffe, in a very interesting Paper read before the Manchester local section, have shown that the resistance of an earth-plate is often very considerable, and that apart from the intervention of non-conducting strata the resistance between two plates each 1½ ft. square, and arranged 200 ft. apart, may be about 30 ohms, so that a leakage current of a few amperes would cause a big drop in potential. Another very important point is that nearly 50 per cent. of this drop occurs within 3 ft. of the plates. It appears all the more necessary, therefore, in earthing the metallic dead portions of any system to provide several earth-plates distributed over the installation. Also, Messrs. Cunliffe's results show that there is no great advantage in making each plate more than about 4 sq. ft. in area.

Danger of Faulty Insulation.—There is, however, a possible danger

* Paper (slightly abbreviated) read before the Institution of Electrical Engineers last night and before the Newcastle local section on Monday last.

Digitized by Google

of shock which cannot be guarded against in this way, and that is by coming in contact with faulty insulation, such as an unarmoured damaged cable. With an earthed system shock as before is certain, with an insulated system it is likely to be less severe. Where cables are armoured or enclosed in a metallic covering this danger cannot occur as long as the armouring or cover are efficiently earthed and electrically continuous. If, however, a careless jointer leaves the armouring disconnected after a hurried repair, or the armouring is eaten away by bad water, &c., the conditions are now more dangerous than before, as an earth may cause a considerable length of armouring to be alive, any part of which will give a shock. For this reason many colliery engineers object strongly to the use of armoured cables as being likely to produce a false feeling of security.

Danger from Explosion.—It is very doubtful whether many colliery managers would instal electric plant at all in places where there is real and constant danger of inflammable gas or coal dust, as it seems fairly certain from recent experiments that an arc or flash with any moderate amount of power behind it will ignite either gas or coal dust in suspension if present in suitable proportions. With an earthed neutral failure of the insulation of one phase to earth is practically bound to produce such a flash, while with an insulated system an earth on one phase shows on the leakage indicator, and there is, at any rate, a greater chance of isolating the section before any arc occurs.

Reliability of Supply.—It is sometimes desirable to run certain plant, even although it may be in a damaged condition. The stoppage of, say, a main haulage gear will disastrously affect the day's output of coal—a matter of very great importance to the colliery manager—and very possibly if the plant can be kept going for a few hours till the end of the shift the fault can then be remedied without disorganising the working of the pit. In many such cases it may be perfectly safe and advisable to run, and as the majority of failures of colliery plant are leakages to earth, an installation with earthed neutral is likely to give more trouble than an insulated system. If leakage trips are indiscriminately used, it is probable that unnecessary interruptions from trivial causes may be sufficiently troublesome to prejudice the manager against electricity and lead him to adopt some other motive power.

Leakage Tripping Devices.—Several very interesting devices have been recently put on the market arranged to cut off current as soon as any leakage current exceeding, say, $\frac{1}{4}$ ampere flows. They are only designed for use on a system with a neutral earthed either directly or through a resistance, and the current at which they operate can be adjusted to different values on different feeders as may be required. It is claimed that by using such switches in connection with armoured cables danger from shock and explosion is largely avoided, and Mr. Wedmore, in a Paper read at Barnsley, gave the results of some very useful experiments on cables which tended to show that with such a device and armoured cables it was very unlikely that a fall of the roof could so damage the cable as to cause flashing or arcing externally. Even without the leakage trips and with only the ordinary overload devices it appeared to be generally necessary to subject the cable to "successive blows of a heavy hammer" before flame occasionally issued, and apparently also high-tension supply was safer in this respect than medium pressure. In case a cable were actually suddenly severed, it seems hardly possible that a flash of sufficient energy to ignite an explosive mixture could be avoided, whether a leakage trip was installed or not, and particularly if the point of failure was comparatively near generating plant of large capacity. It must be borne in mind, however, that many cables are run in places where there is no danger of explosion or of mechanical injury. It must be also noted that these devices depend absolutely on the continuity of the armouring or earthing being maintained, and if through carelessness or other cause this is not done they afford little protection against explosion and practically none against shock. A motor standing on concrete foundations is on a very good insulator, and if the earth connection is broken or inoperative insufficient current would flow to operate the leakage trip in case of leakage to the motor frame, which would then be raised above earth potential. We have previously seen that as long as earth connections are kept in good order there is no danger of shock from motor or switch casings or armouring, so that while there are undoubtedly many cases in which a leakage device may be of considerable use there are also many others where it would not justify the increased expenditure and would probably prove rather a nuisance. These devices, moreover, do not protect against shock from live terminals or from contact with a high-resistance leakage.

Simplicity of Installation.—In the author's opinion the simpler the installation can be made the more likely it is to be kept in good working order, and it has generally been found in the past that it is better to rely upon having good men to look after the plant and see that small details such as earthing, &c., are properly attended to than on automatic appliances.

Stress on Insulation.—As long as a system with insulated neutral is in good order the stress on the insulation is 16 per cent. less than on an earthed system, so that under equal conditions its factor of safety is greater. There is no doubt also that much greater clearances and creeping distances to all metal work must be provided where the neutral is earthed, to give the same factor of safety as on insulated systems. The advantage of the earthed system is that an earth on one phase soon isolates the faulty part, and does not increase the stress on the other parts of the system, while a similar occurrence on an insulated system doubles the stress on the other places and is likely to cause further breakdowns. This point is of greater importance on extra high voltages.

Cost of Installation.—While not necessarily the first consideration, the question of cost in all engineering problems is of very great importance and one that will not be neglected by the colliery manager, whose business it is to get the best possible financial results. Where automatic oil switches are used, three relays, one in each phase, are needed with an earthed neutral, and only two with an insulated neutral. If many switches are needed, the difference in first cost may be considerable. The cost of armoured cable is often nearly double that of unarmoured, so that if these are run in places where there is is no danger of accidental contact, damage from falls of roof or sets off the line or of explosion, armouring is an unjustifiable expense. The cost of maintenance is generally of greater importance than first cost, and it is here that the simplicity of the installation is of primary importance.

Conclusions.—No hard-and-fast rules can be laid down, and every case should be considered broadly on its merits, but it certainly seems that generally an insulated neutral is better where permanent plant is at work and the cables are not very liable to mechanical damage. Where portable machines such as coal-cutters are used, or where cables are liable to frequent hard usage, it may be worth while to use automatic devices; and in this case, if a separate transformer were used to supply this plant, its neutral could be earthed (and preferably through a resistance) without interfering with the remainder of the system. Such devices, however, will require constant inspection. There is another very important case which has not so far been considered, and that is where small lighting transformers are used. It would seem desirable to limit the secondary pressure of these to 110 volts and connect either the neutral or one side directly to earth. Finally, the author wishes to disclaim any sympathy with the present scare in regard to the use of electricity in mines. It is necessary in a Paper of this sort to consider how accidents can and may occur, but the number that actually do occur is extraordinarily small considering the present widespread use of electricity and the insufficient electrical staff employed in many collieries. The average number of deaths caused by the use of electricity in mines appears to be about 1 per cent. of all the accidental deaths in such places, and many of these cases have been due simply to pure accident or carelessness which nothing could have prevented.

TELEGRAPHY OF PHOTOGRAPHS, WIRELESS AND BY WIRE.*

BY T. THORNE BAKER.

Summary.—The lecturer first describes the telectrograph system as used by the "Daily Mirror," explaining the method of overcoming the effect of capacity in the lines. He then refers to the work of Prof. Korn with selenium cells, and finally gives particulars of the experiments in wireless transmission upon which he (the lecturer) has recently been engaged.

It frequently happens that when two alternate processes are available for certain work, and one of them is considerably less practical than the other, that the less practical one is possessed of much higher scientific interest. This may certainly be said of the telegraphy of pictures and photographs. The whole of the methods of transmission can be classed as either purely mechanical, or dependent on the physical properties of some substance which like selenium, is sensitive to light. The latter methods are of no little scientific interest, and, although very delicate and for the moment obsolete, there is every likelihood of their coming into more extended use later on.

I propose to deal with the practical more system first. The telectrograph system has been employed by the "Daily Mirror" for

* Abstract of a lecture delivered at the Royal Institution last Friday evening.

Digitized by Google

the transmission of photographs since July, 1909, and has been worked very regularly between Paris and London, and Manchester and London. The method of telegraphing photographs that has been employed on a large scale by the "Daily Mirror" may be called a practical modification of several early attempts. The effect of an electric current to discolour certain suitable electrolytes or to set free an element or ion that can be used to form with a second substance a coloured product was employed in many early forms of instruments for telegraphing writing, &c. If we break up a photographic image into lines which interrupt the current for periods depending on their width, these interrupted currents can be used at the receiving station to form coloured marks which join up *en masse* to form a new image. My telectrographic process is thus briefly as follows :—

At the sending station we have a metal drum revolving under an iridium stylus, to the drum being attached a half-tone photograph printed on lead foil. Current flows through the photographic image to the line and thence to the receiver. The receiver consists of a similar revolving metal drum over which a platinum stylus traces. Every time the transmitter stylus comes in contact with a clear part of the metal foil current flows to the receiver, and a black or coloured dot or mark appears on the chemical paper. But you will readily understand that if our reproduction—built up of these little marks, which have to be made at the rate of some 200 per sec.—is to be accurate, each mark must be only exactly as long, in proportion, as the clear metal space traversed by the stylus.

It will be easier to explain the system by means of the rough diagram shown in Fig. 1. A metal drum is revolved by a motor, one revolution every two seconds ; over this a metal stylus or needle traces a spiral path in the same way as a phonograph. On the drum is fixed a half-tone photograph broken up into lines, and printed in fish glue upon a sheet of lead foil (in these line photographs the light and shade of the picture is made up of masses of thinner or thicker lines, with clear spaces in between). As the stylus traces over such a photograph, its contact with the metal base is interrupted every

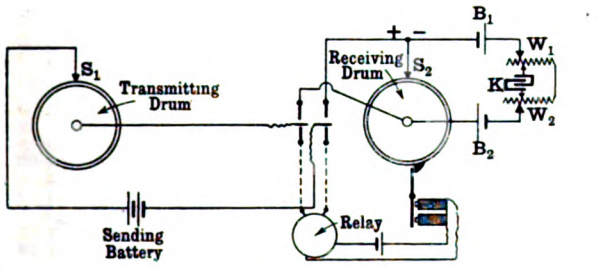

FIG. 1.

time one of these fish-glue lines comes beneath it, and for such a time as depends, of course, on the width of the line. The transmitting instrument thus sends into the telegraph lines a series of electric currents whose periods of duration are determined by the width of the lines composing the photograph. A similar stylus S_2 traces an exactly similar path over a revolving drum in the receiving instrument, but round this drum is wrapped a piece of absorbent paper impregnated with a colourless solution, which turns black or brown when decomposed by an electric current. What happens then is that every brief current which passes through the paper causes a mark to appear on it. The width of the mark depends on the duration of the current—or should do—so that these marks gradually combine to recompose the photographic image.

This method is all very well in the laboratory, but when we come to try it over a long distance the capacity of the line at once causes serious interference. If the circuit be closed by means of a Morse key, the time of contact at the key being $\frac{1}{6}$ sec.,—a common time of duration of a short tap—the discharge of current from the cable would be considerably longer than $\frac{1}{6}$ sec. When, therefore, we are sending signals through the line at the rate of 175 per sec., it is not difficult to see that every signal will run into the next dozen or so at the receiving apparatus, and the result will be a hopelessly confused mass of overlapping marks. The use at the receiver of what I have termed a line balancer, a modified form of shunt apparatus embodying the principles of *wiping out* residuary currents from the cable in the way frequently made use of in duplex telegraphy, has rendered commercial the old ideas of telegraphing by the electrolytic method, and as many as 300 sharply defined chemical marks can be recorded in 1 sec. by its means. The method of application will be seen from Fig. 1, here shunted on to the line (which is closed by the stylus S_2 and the metal drum) is a circuit containing two batteries B_1 and B_2 and the two sections of a divided 1,000 ohms resistance, W_1 and W_2. Shunted across the variable contacts of the resistances is a variable condenser K. By varying the resistances W_1 and W_2 we can vary the power of the current used to sweep out the residuary charges in the line ; the current can, of course, flow through the chemical paper on the drum, but the pole of the battery B, connected to the stylus is of opposite sign to that of the line unit connected to it. When the leakance on the line is great and evenly distributed, less reverse current from the balancer is necessary, this being quite in accordance with Heaviside's formulæ for telephony over lines with capacity and inductance. It is interesting to note, also, that by increasing the voltage of the reverse batteries, B_1 and B_2, considerably greater contrast can be obtained in the pictures ; the finer the half-tone screen employed in splitting up the photographs into lines, the higher, again, must the voltage of B_1 and B_2 be made.

The lecturer here again referred to the actual utility of photo-telegraphy. News is telegraphed in order to expedite its publication, and photographs illustrating this news can therefore be telegraphed advantageously. But where a large installation and establishment with accumulators, a large instrument and an operator to work it are required, the cost of telegraphing every individual picture becomes quite out of proportion to its value. The lecturer therefore called especial attention to portable instruments, the first one of which was shown. A photographer going to obtain pictures of some important function or interesting event can take this machine with him, prepare his pictures and telegraph them to his head office, and when the event is over return with the apparatus. For criminal investigations the portable instrument should become of considerable value. Through the continued courtesy shown by the Postmaster-General and Major O'Meara every facility has been given for developing the work, and the uses of the portable instrument should before long have been amply demonstrated.

If a picture revolving beneath a tracer has to redraw itself, as it were, on a piece of paper perhaps hundreds of miles away, it is obvious that each mark redrawn must occupy a precisely similar spot on the new paper as it does in the original picture. As cylinders or drums are used in picture telegraphy, this means that they must revolve in perfect unison. The method of synchronising used by

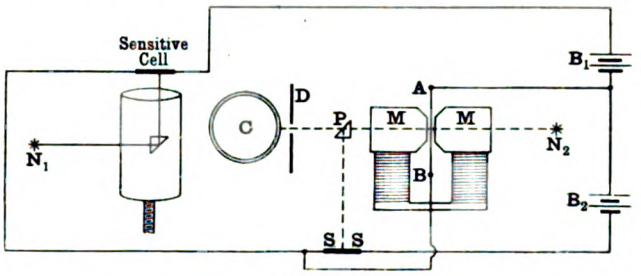

FIG. 2.

Prof. Korn has proved very satisfactory, and has been adopted in practically all systems of phototelegraphy. The motors which drive each drum are run at about 3,000 revs. per min., and geared down very considerably, so that the drums themselves revolve, perhaps, at 30 revs. per min. ; the motors are run from secondary batteries and should be run for a sufficient time before beginning a transmission to allow of their warming up. The speed of each motor is controlled by a regulating resistance in series with the field magnets, and the speed is ascertained by means of a frequency meter.

The receiving drum is revolved a little quicker than the transmitting drum. It consequently completes its revolution before the transmitter. It is then stopped by a steel check, and is obliged to wait until the other drum has caught it up. When the transmitting drum has completed its turn, a fleeting contact comes into play, a reverse current is sent to the receiving instrument, this is led into a polarised relay which actuates an electromagnet, and this magnet removes the check. Thus both drums must always start off in unison for each new revolution. I have found that where each operator endeavours to keep his motor running uniformly by regulating the resistance according to the fluctuations recorded by the frequency meter, the personal element makes itself visible in the results ; straight lines appear wavy, and the synchronism is not at all good. I therefore tried very carefully calibrating the motors by timing first, and then arranged that, once started, the motors should not be touched ; the gain in speed of each is approximately the same if both motors are run from secondary batteries of the same ampere-hour capacity, and in this way we have obtained the most perfect results as regards synchronisation.

The great advantage of this process is that the whole operation is in full view, whereas with systems in which the received picture is obtained on a photographic film one has to develop such film before it is possible to discover whether anything is wrong. With the receiver described, the operator keeps his hand on the sliding contact of the resistances, and merely adjusts their position during the first two or three seconds according to the condition of the

Digitized by Google

electrolytic marks—*i.e.*, whether crisp and concise or not. The transmitting cylinder can be used as the receiving cylinder, and the apparatus is thus reduced to the limits of simplicity.

Towards the end of last year I designed a portable machine, two of which Mr. Sanger-Shepherd has just completed, embodying in them a number of improvements of his own, and these machines, which have worked successfully on their trials, are shown. They are suitable for line or wireless work, and will, I believe, prove of great value in naval and military operations.

The "Daily Mirror" inaugurated the Paris-London photographic service in November, 1907, with Prof. Korn's selenium instruments. In this system use is made of the fact that the electrical resistance of the metal selenium varies according to the strength of illumination to which it is subjected, a beam of light passed through the light and dark parts of a photograph in succession being used to vary the strength of an electric current sent to the receiving apparatus. The transmitter light is concentrated from a Nernst lamp to pass through a revolving glass cylinder, round which a transparent photograph (printed on celluloid) is fixed, the beam traversing the film at its brightest part, where the rays come to a focus. The light which passes through the picture is reflected by a prism inside the cylinder on to the selenium cell, through which the current passes. Across the circuit is shunted a galvanometer of the Einthoven pattern, containing two fine silver strings free to move laterally in a strong magnetic field. These are represented by AB, the magnet poles being MM. When a bright part of the photograph admits of light falling on the sensitive cell current passes through AB, and it shifts aside, allowing light from a Nernst lamp N_2 to enter the prism P, whence it is reflected on to a second cell SS. The telephone lines connecting the two instruments go direct to the wires of a similar galvanometer, which is in series with the galvanometer of the transmitting instrument. If we imagine MM to be the receiving galvanometer, then we remove the prism P, and the light acts on a sensitive photographic film attached to the drum C, which revolves synchronously with the glass cylinder of the sending instrument.

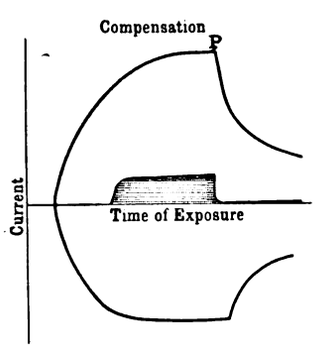

FIG. 3.

The inertia of selenium once overcome, the metal immediately becomes of great use for many purposes. Prof. Korn's method of compensation is to let the light fall at the same time on two cells of opposite characteristics; one has great inertia and small sensitiveness, the other low inertia and great sensitiveness. By using the two cells on opposite sides of a Wheatstone bridge, dividing the battery into two parts for the other sides, the deflection in the galvanometer is very rapid. The effect is shown in Fig. 3. The curve above the axis along which exposure is measured relates to the sensitive cell, that below this axis, to the cell of low sensitiveness. Clearly the current passed through the galvanometer is that obtained by joining the sums of the ordinates. This gives the small curve shown as the shaded portion. When the illumination is thrown on the cell the current rises very rapidly instead of gradually, whilst when it is suddenly shut off (at P in the upper curve) it drops to zero almost instantly instead of falling gradually. This enables the cells to be used for the purposes of photo-telegraphy, where at least half a dozen changes per second are required to be recorded abruptly, even in transmitting the simple portraits to which the selenium process is limited.

This compensated arrangement of selenium cells at once renders their use of practical value for various physical and optical measurements. Prof. Korn has found that for an increase in the illumination δI, the current obtained is given by the equation $y = a \cdot \delta I \cdot e^{-\beta t^{-\frac{1}{m}}}$, where y is the current, a the sensitiveness of the cell, β and m its inertia constants, and e the base of Naperian logarithms. For two cells to be combined to the greatest advantage we must have them such that if their equations are respectively

$$y_1 = a_1 \delta I \cdot e^{-\beta_1 m^{-\frac{1}{t}}} \text{ and } y_2 = a_2 \delta I \cdot e^{-\beta_2 n^{-\frac{1}{t}}}, \text{ then } \frac{d(y_1 - y_2)}{dt} = 0.$$

This makes the condition for good compensation that $a_1 \beta_1 = a_2 \beta_2$; m is usually almost constant, and with suitable Giltay cells is about 2·3. In practical language, the condition for compensation is that the principal cell should have great sensitiveness and a small inertia constant, the compensation cell low sensitiveness and a high inertia constant, the product of sensitiveness and inertia constant being the same in the case of both cells.

The physical properties of selenium are of such importance that I feel I may be allowed to digress for a few moments to show one way in which they may be utilised to solve a problem that has long occupied many investigators—viz., the satisfactory measurement of the beam of heterogeneous rays from an X-ray tube. If the X-rays fall on a fluorescent screen of barium platino-cyanide, the screen absorbs them and emits yellowish-green visible rays; this transformed energy is capable of affecting a very sensitive selenium cell when placed in contact with the screen, the resistance becoming less the greater the fluorescence. I will take a selenium cell of approximately 395,000 ohms resistance, over which is placed a small fluorescent screen of the same size; the cell is put in series with a battery of 100 volts pressure, and a milliampere meter, the divisions of which may be made to correspond to some arbitrary scale, or to the time necessary for the exposure of a given make of photographic plate. The dividing of the scale depends on two things: first, the characteristic curve of the selenium cell connecting its resistance with the strength of illumination, the linear distance of the source from the cell being in this case the most convenient to employ. Secondly, this characteristic curve must be modified to meet the case of illumination by the rays from the anti-cathode, which do not necessarily diminish in their power to make the screen fluoresce as the square of the distance from it. Fig. 4 shows the characteristic curve of a selected selenium cell for feeble illumination, the maximum being of about the same wave-length as that of the fluorescence, showing the relation between the current and distance separating the source of illumination and the cell; and Fig. 5 the modified curve showing a similar relation between the current and distance between anti-cathode and cell, with the screen in contact. The portion of the first curve most nearly asymptotic is best to employ for the work, and from the second curve the scale of the meter can be easily calibrated. The actual instrument is provided with a scale divided so as to show

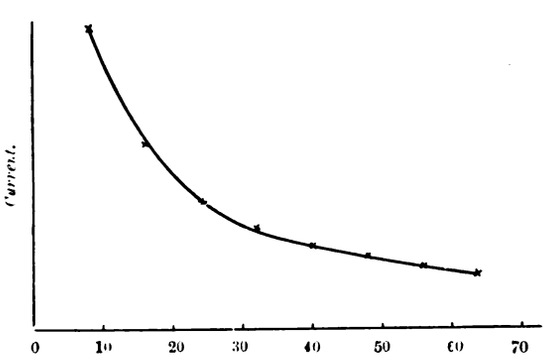

FIG. 4.—CURVE SHOWING EFFECT OF FEEBLE ILLUMINATION ON THE RESISTANCE OF SELENIUM. Giltay Cell.

Resistance of Unilluminated Cell, 395,000 ohms.

comparative times of exposure, and by its use radiographic work can be greatly facilitated.

It is interesting to note that the effect of the rays on the fluorescent screen, as estimated by the selenium cell, differs less with increasing distance, the further the anti-cathode is from it:—

Distance of anti-cathode from apparatus.	Current recorded in milliamperes.	Difference.

14	0·18	0·02
16	0·16	0·02

The lecturer next showed some of the photographic results with the selenium apparatus of the "Daily Mirror" installation.

Late in 1908 Prof. Korn introduced his telautograph, in which a Caselli transmitter, such as already described for the telectrograph is used, and a line sketch or half-tone photograph is attached to the drum. The receiver is similar to that used in the selenium machines, a spot of light cast on a revolving sensitive film being shut off every time current flows through the wire of the galvanometer and displaces it; when displaced the shadow of the wire falls over a fine slit placed in front of the film, and so prevents the light from passing through to it. The methods of synchronising the sending and receiving cylinders is the same as that used in the telectrograph, but Prof. Korn's work was done prior to mine, and his arrangements were therefore copied by me. Similar methods have been adopted for many years, however, in certain systems of ordinary telegraphy.

Wireless Transmission.

The wireless apparatus I have used for transmitting sketches, writing, or simple photographic images over distances up to about 50 miles may perhaps be looked upon as rather rudimentary, but it is at any rate practicable. The following experiment illustrates clearly how easy it really is to transmit a photograph by wireless under ideal conditions. I have here a small electric lamp, coupled up with the local side of a relay and battery, the relay being actuated by means of a coherer detector. At the other side of the platform there is a Morse key, which, when depressed, closes the primary circuit of an induction coil, the secondary being coupled up in the usual way to give oscillations. When I press the key, and thereby send a signal, you see that the lamp at once lights up. If the coherer be tapped the lamp is extinguished, and another tap of the Morse key causes it to light again. Now suppose that the taps of the Morse key were controlled by the lines in a photograph or sketch, and that the light from the lamp were concentrated on a revolving photographic film, and you will see at once how a photograph could be transmitted by wireless telegraphy.

Such a process would be utterly impracticable commercially, but my telectrographic system can be used with success in its place. A line picture is attached to the drum of the transmitter, and the intermittent current which is ordinarily passed into the telephone line goes into an electromagnet (M in Fig. 6), which then attracts a soft iron diaphragm attached to brass springs, which are fixed to two rigid supports. Every time current flows through the magnet coils this diaphragm is attracted to it, and the platinum contacts PQ are brought together; when the current flows, and PQ are in contact, the primary circuit of a transformer is closed, and the secondary having a spark gap and being inductively coupled to the aerial and earth, a signal is transmitted into space. Thus, in the wireless transmitter the only difference from ordinary telegraphy lies in the fact that the length of the signals and their distance apart is regulated by the lines composing the sketch or photograph.

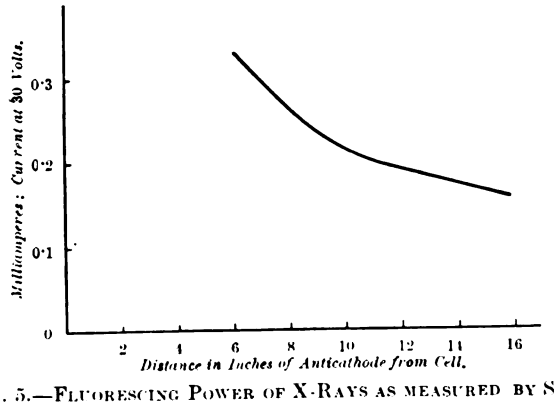

Fig. 5.—Fluorescing Power of X-Rays as measured by Selenium.

When working with high voltages in the primary, such as 110, arcing is liable to take place, and hence the distance between P and Q when not attracted must be considerable. This means that the distance between the diaphragm clamps must be short, and the German-silver spring of which the diaphragm is made must be thick, these two conditions making the natural period of vibration very short. I have, however, found that by interposing a mercury motor-interrupter in the primary circuit, arcing is almost entirely avoided.

The receiving apparatus is very simple, and depends, for short-distance work, upon a coherer cymoscope, the decohering apparatus being of a particular character. Every time an oscillation passes to the antenna, the coherer becomes conductive in the ordinary way, and a relay is actuated; this relay is usually made to start a hammer vibrating, the hammer hitting the coherer, and thus causing it to lose its conductive power. But a vibrating hammer is useless for the photo-telegraphic receiver, and it is essential to have one strike only on the coherer for each signal detected.

The form of apparatus I have employed for this purpose is seen diagrammatically in Fig. 7. EE is the magnet which is actuated by the relay R. It then attracts an armature MN, which moves towards the magnet poles and brings a resilient hammer, H, fitted with a platinum contact, P, against the coherer. The coherer AB is also fitted with a collar, F, and contact pin, so that in the act of striking the coherer the hammer closes a local circuit, and so causes a black mark to appear on the chemical paper. Successive distinct marks can be obtained in 0·017 sec. in this way, which is considerably more rapid, I believe, than a decoherer was given credit for.

Only sketches of the simplest character are at present being transmitted, but as you will see from the result thrown on the screen—a simple portrait of His Majesty the King—the images are recognisable, and merely require slightly more detail to make them quite comparable with the early results in line obtained by Prof. Korn's tel-autograph. Another result showed a plan transmitted by wireless. Such plans could be drawn direct in shellac ink on a slip of metallic foil, placed upon a portable machine coupled to a portable military wireless set, and communicated from one section of an army to another. The small portable machines I have already shown are used for the wireless transmissions, and they possess the advantage that "tapping" of the communications would be quite impossible. It is for this reason that I think the method would be of such value for military and naval purposes; even supposing that anyone wishing to intercept a plan or written message were to have an exactly similar instrument, with the same dimensions, by merely altering the rate of running by 5 or 10 per cent., according to prearranged signals, the picture as received by the intercepting party would be quite unintelligible and confused.

When dealing with wireless work the question of synchronism becomes more serious. I have employed two methods, each of which

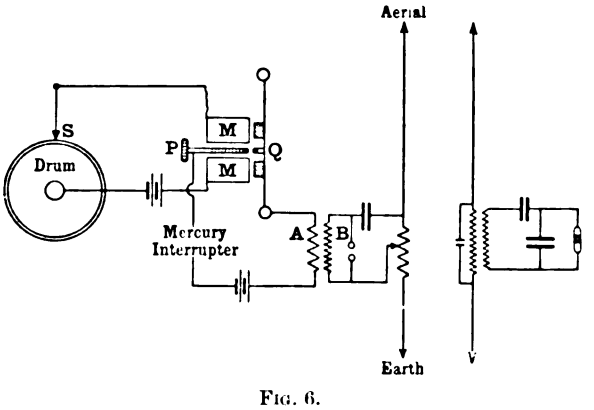

Fig. 6.

appears to answer satisfactorily. The first method secures accurate synchronism independently of any wireless communication. You have already seen how, in the ordinary telegraphic work, the receiving cylinder is driven rather faster than the sending one, and when it finishes up a complete turn too soon it is arrested until the sending cylinder has caught it up, when the latter sends a reverse current which is responsible for its release. In the wireless apparatus both sending and receiving cylinders are driven too fast, so to speak—that is, they are made to revolve in 4¾ secs. instead of a nominal 5. A check comes into play at the end of the revolution, and the cylinder is stopped until the 5 secs. are completed, the motor working against a friction clutch in the ordinary way during the stop. At the end of ½ sec. each cylinder is automatically released by chronometric means, as shown in Fig. 8. A special form of clock is used, with a centre seconds hand which projects beyond the face by about 1 in., and to the end of it is attached a brush of exceedingly fine silver wires. At every $\frac{1}{12}$ part of the circumference of the clock dial is fixed a platinum pin, and consequently every 5 sec. the little brush wipes against the convex surface of one of them. Each of these pins is connected with one terminal of a battery, the other

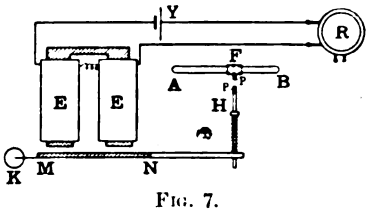

Fig. 7.

side of the battery leading to the relay, as does also the centre seconds hand. Therefore each time the brush wipes against a pin the circuit is closed, and the relay throws into action the local circuit connected up with its terminals. This circuit excites an electromagnet, which attracts an armature and pulls away the check which is holding back the cylinder. At the end of each 5 sec. the cylinders consequently recommence turning. Well calibrated clocks of the pattern used will keep good time for the period taken to transmit a picture, one gaining on the other quite an inappreciable amount, depending on the friction of the brush against the pins.

The other method of synchronising is controlled by electromagnetic oscillations. Let us suppose that a coherer is being used as cymoscope, the transmitting cylinder is kept running without any interruption, but by means of a fleeting contact it sends out a wave at the conclusion of its turn, a bare space in the picture being necessary about ½ sec. beforehand, so that no waves are sent out for the

Digitized by Google

½ sec. previously. The receiving cylinder is driven too quickly and checked at the end of the revolution. It then, by means of a cam pressing down a spring lever, throws out of circuit the marking current and brings into circuit the relay which actuates the electromagnetic release. Consequently, when the synchronising wave is received, the coherer causes the relay to work, the release is effected, and the receiving cylinder starts a new revolution in unison with the transmitter. This means of synchronising is only possible in cases where a cymoscope is employed that is capable of actuating a relay, and you will therefore see that it is out of the question except for short distances. I am therefore using the chronometric system already described in the apparatus, and it is being embodied in the quartz fibre apparatus described below. I must first remark that the wireless work has been greatly facilitated by the courteous assistance so readily given by the Marconi Company.

The general form of the Einthoven galvanometer is well known, and the modified type of it used by Prof. Korn for photo-telegraphic purposes has been shown. If, now, we make the magnetic field very much more intense by building the field magnets heavier, and using a large number of ampere-turns in the winding, and also employ a "string," which is very much more elastic than the silver ribbon, the displacement of the string will be correspondingly greater. The silvered quartz fibre used by Duddell for this purpose gives an extremely sensitive instrument, and very appreciable displacement is obtained with the current from one dry cell passing through 35 to 90 megohms resistance. It is not long since Prof. Fleming explained at this Institution the valve receiver for detecting wireless oscillations; in ordinary wireless telegraphy the minute alternating currents are rectified, and sounds are heard in the telephone in circuit owing to small uni-directional currents. If these currents be passed through the silvered quartz string of the galvanometer the string is shifted. If, therefore, we cause a shadow of the string to lie over a fine slit, any displacement will cause the slit to be opened, as it were;

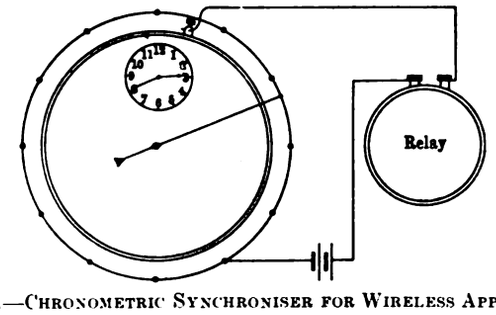

Fig. 8.—Chronometric Synchroniser for Wireless Apparatus.

the shadow will be shifted off the slit, and light will be free to pass through it. Oscillations corresponding to the lines in a photograph or sketch could therefore be utilised to cause shifting of the shutter in the manner I have already described for Korn's telautograph, and a sensitive photographic film could be revolved on a drum behind the slit to receive the picture. Such an apparatus is now in course of preparation, but the amount of light that passes through the slit is extremely small, owing to the fineness of the fibre. Mr. Sanger-Shepherd has therefore attached a minute shutter to the fibre, crossing the optic axis; this enables me to use a very much wider slit, and also to adopt the alternative procedure for reception. The oscillation is passed into the valve detector, and thence to the quartz fibre, which is stretched across the field of the magnets, whose poles are bored with a tunnel through which the beam of light is directed. When the fibre is displaced light is enabled to pass through a fine slit, and so act on the photographic film. Where, however, the shutter is attached to the fibre a much wider slit can be used, and then a pair of narrow compensated selenium cells are placed behind the slit, a positive lens being interposed. When a signal corresponding to a dot in the photograph—*i.e.*, the traversal of a line by the stylus—is received, the fibre shifts, light falls on the cells, and their resistance is decreased sufficiently to enable the battery to actuate the relay. This closes a local circuit, in which the telectrograph receiver is included, and a mark appears on the paper. In this way a visible record is obtained, which greatly facilitates the process.

Wireless photo-telegraphy may eventually prove of more utility than the closed-circuit methods, because it would bring America within reach of this country, and would enable communication to be made where telephone or telegraph lines did not exist. It is not limited to photographs—banking signatures, sketches, maps, plans and writing could be transmitted. But I would point out most particularly that the work is as yet in the very earliest stages, and that in giving you some account of it to-night I may be bringing before your notice methods and systems on which a few years' hence you will look back with a smile—as curious merely from a historical point of view.

LEAKAGE REACTANCE.

BY J. REZELMAN.

Summary.—The author supplements his recent article on "Leakage Reactance" with the test results of the reactance of a four-pole stator winding with special end connections. The results confirm his conclusions on the mutual induction between phases.

The Mutual Induction between Phases.

The author has thought it useful to describe experiments carried out on a new machine with special arrangement of the end connections; these experiments complete his previous

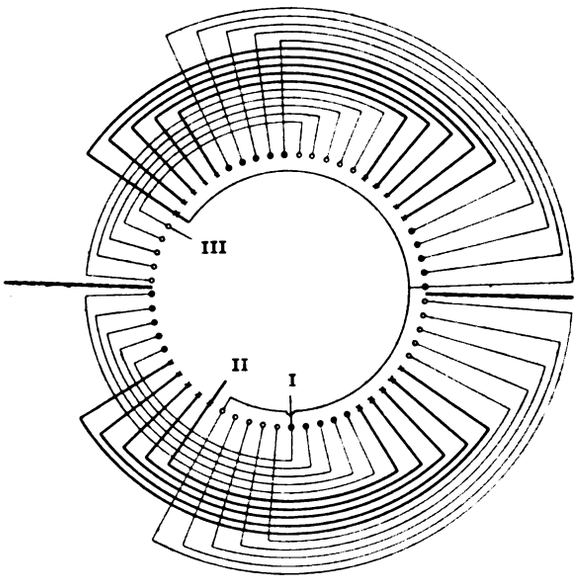

Fig. 1A.—Special Consequent Pole Winding in Three Planes.

study of leakage reactance,* and at the same time confirm the results already obtained on the mutual inductance between the phases.

Stator of a Three-phase Turbo-alternator 4,000 k.v.a., 4 poles, 50 ~ per second, 1,500 revs. per min. 6,600 volts between phases, the rotor being out.

Dimensions.—$\phi_i = 1{,}034$ mm., $\tau = 812$ mm., $l = 1{,}050 - 26 \times 7{\cdot}5$ mm., $l_i = 950$ mm., 60 slots, open type (22×73), $t_1 = 54{\cdot}2$ mm, $s_n = 5$, $p = 2$, $q = 5$.

The stator is wound with consequent poles, that is to say, there are two coils per phase for the four poles; the end connections of the five slots thus form one coil, only, since the

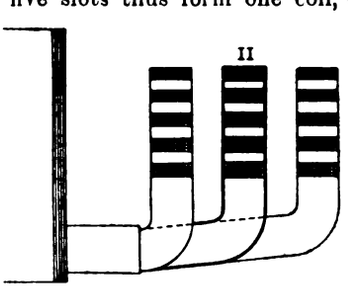

Fig. 1B.—Special Consequent Pole Winding in Three Planes.

frame of this alternator is in two pieces, it was necessary to arrange the end connections *un*symmetrically, and in three planes, in order that each half could be completely wound before assembling. The end connections of phase I. and III. are arranged just as is customary in the case of a consequent pole winding, whilst those of the remaining phase (II), instead of crossing over the joint, are bent back in the *opposite* direction. Figs. 1A and 2.

Fig. 3 shows the direction of the current in phases I. and III. when connected in series; we see then that the parts *a* are traversed by currents in opposite directions, there is, therefore a *negative* mutual induction; the parts *c* are traversed by currents in the same direction which produce a *positive* mutual

* *See* The Electrician, August 20 and 27, 1909.

Digitized by Google

induction. The mutual induction of the part c is thus in opposition to that of the part a, and they counteract one another to a great extent.

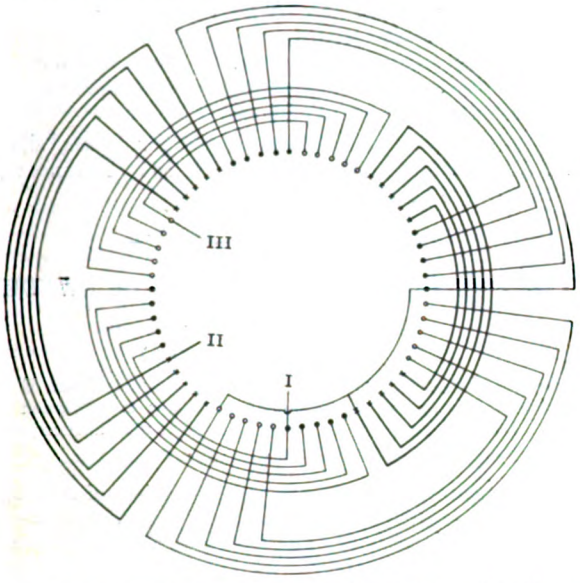

Fig. 2.—Ordinary Consequent Pole Winding in Two Planes.

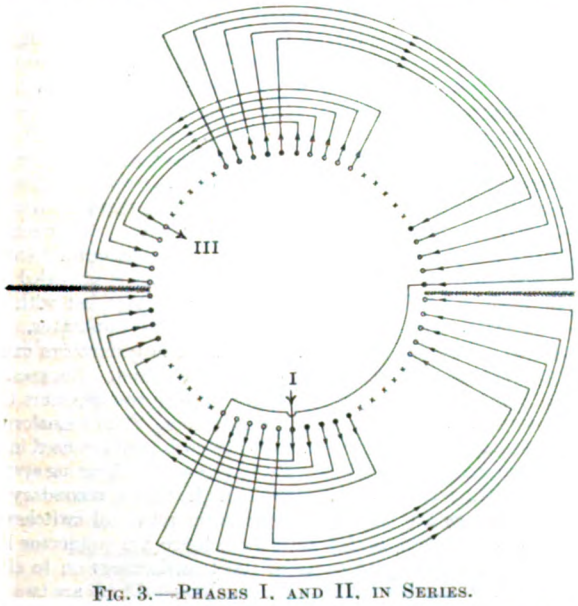

Fig. 3.—Phases I. and II. in Series.

With phases I.—II. and II.—III. connected in series this is not the case (Fig. 4); the parts a and c are now traversed by urrents in the *same* direction, there is thus a *positive* mutual in-

duction in both cases, and, moreover, for a *considerable* length of end connections. The external length of the coils is the same for the two coils of phase II: $l_s = 1{,}860$ mm.; with the

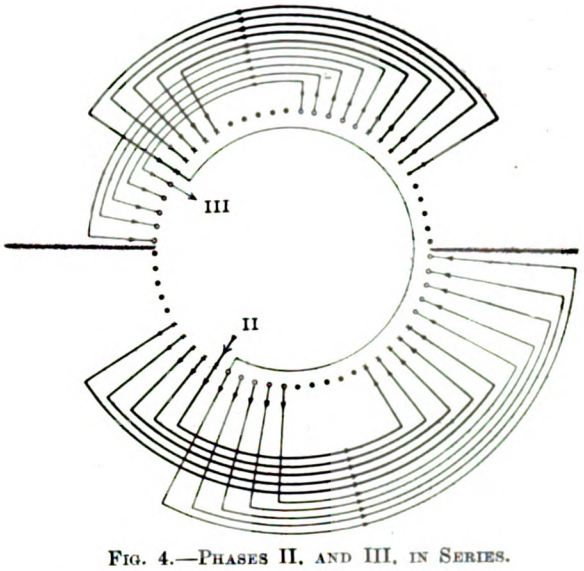

Fig. 4.—Phases II. and III. in Series.

two other phases there is in each case a short coil near to the core and a long coil away from the core. Their *mean* length, however, is *equal* to that of phase II.

The length l_s may be divided into l_{s_a} and l_{s_c}, and we have $l_{s_a} = 1{,}060$ mm., $U_{s_a} = 440$ mm., $l_{s_c} = 800$ mm., $U_{s_c} = 650$ mm.

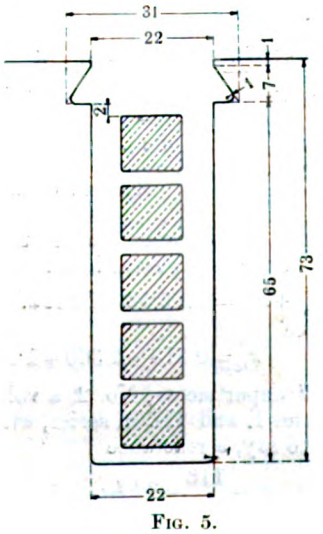

Fig. 5.

Experiments.—Measurements were taken on *each* phase with end shields removed.

1. Single-phase per phase.
2. Single-phase two phases in series.
3. Three-phase.

Separation of the Voltages.

1. *Single phase per phase.*—The machine has *open* slots (Fig. 5). We have then

$$\lambda_s = 1{\cdot}25\left(\frac{63}{66} + \frac{2}{22} + \frac{2\times 7}{31+22} + \frac{1}{22}\right) = 1{\cdot}695$$

for a length $l_s = l_i = 95$; whence

$$x_{s_a} = \frac{12.5 \times 51 \times 50^2}{2\times 5\times 10^8} \times 95 \times 1{\cdot}695 = 0{\cdot}257\omega.$$

For five slots per pole and phase,

$$\lambda_k = 0{\cdot}92\left\{\log\left(\frac{\pi \times z_1}{r_1}\right) + 2{\cdot}1 + 5\log\left(\frac{\tau}{4t_1}\times\frac{p+1}{p}\right)\right\}$$

$p=2$, $q=5$.

$$= 0{\cdot}92\left\{\log\left(\frac{\pi\times 32{\cdot}2}{22}\right) + 2{\cdot}1 + 5\log\left(\frac{812}{4\times 54{\cdot}2} + \frac{2+1}{2}\right)\right\}$$

$$= 6 \text{ for a length } l_k = l_i = 95.$$

Digitized by Google

Whence $x_{s_K} = \frac{12{\cdot}5 \times 51 \times 50^2}{2 \times 5 \times 10^8} \times 95 \times 6 = 0{\cdot}908\omega$,

we have

$$\lambda_{s_a} = 0{\cdot}46 q_s \left(\log \frac{2 \times l_s}{U_{s_a}} + A \right) = 0{\cdot}46 \times 5 \left(\log \frac{2 \times 1860}{440} + 0 \right)$$

$= 2{\cdot}13$ for a length $l_{s_a} = 1060$

and $\lambda_{s_c} = 0{\cdot}46 \times q_s \left(\log \frac{2 \times l_s}{U_{s_c}} + A \right) = 0{\cdot}46 \times 5 \left(\log \frac{2 \times 1860}{650} + 0 \right)$

$= 1{\cdot}74$ for a length $l_{s_c} = 800$; $A \simeq 0$ for a consequent pole—hemitropic winding.

$$x_{s_a} = \frac{12{\cdot}5 \times 51 \times 50^2}{2 \times 5 \times 10^8} \times 106 \times 2{\cdot}13 = 0{\cdot}36\omega,$$

$$x_{s_c} = \frac{12{\cdot}5 \times 51 \times 50^2}{2 \times 5 \times 10^8} \times 80 \times 1{\cdot}74 = 0{\cdot}22\omega.$$

$$x_{s_a} + x_{s_c} = 0{\cdot}58\omega.$$

The *total* reactance then becomes

$$x_{s_1} = 0{\cdot}257 + 0{\cdot}908 + 0{\cdot}580 = 1{\cdot}745.$$

The table of experiments, No. *1*, gives 52 volts for 30 amperes, which corresponds to a reactance

$$x_{s_1} = \frac{52}{30} = 1{\cdot}735\omega.$$

2. *Single Phase.—Two Phases in Series.*—The permeance λ_u still has the value of 1·695, whence

$$x_{s_u} = \frac{12{\cdot}5 \times 51 \times 100^2}{2 \times 10 \times 10^8} \times 95 \times 1{\cdot}695 = 0{\cdot}513\omega.$$

For 10 slots per pole and phase;

$$\lambda_i = 0{\cdot}92 \left\{ \log \left(\frac{\pi z_1}{r_1} \right) + 5{\cdot}6 + 10 \log \left(\frac{\tau}{9t_1} \times B \right) \right\}$$

$p = 2$, $q = 10$.

$$= 0{\cdot}92 \left\{ \log \left(\frac{\pi \times 32{\cdot}2}{22} \right) + 5{\cdot}6 + 10 \log \left(\frac{812}{9 \times 54{\cdot}2} \times 1 \right) \right\}$$

$= 7{\cdot}8$ for a length $l_k = l_i = 95$; $B \sim 1$ for a winding covering two-thirds of the pole pitch.

$$x_{s_k} = \frac{12{\cdot}5 \times 51 \times 100^2}{2 \times 10 \times 10^8} \times 95 \times 7{\cdot}8 = 2{\cdot}360\omega.$$

With *no* mutual induction between phases the reactance of the end connections of the two phases in series would be:

$$2(x_{s_a} + x_{s_c}) = 2 \times 0{\cdot}58 = 1{\cdot}160\omega.$$

and the *total* reactance

$$x_{s_2} = 0{\cdot}513 + 2{\cdot}360 + 1{\cdot}160 = 4{\cdot}033\omega.$$

From the table of experiments, No. 2, a voltage of *118* is obtained for the phases I. and III. in series, with a current of 30 amperes, that is to say, a reactance

$$x_{s_2} = \frac{118}{30} = 3{\cdot}94\omega.$$

from which it follows that the mutual induction between the phases is *in reality* negligible.

For phases I. and II. or II. and III. the voltage is increased to *137* volts for *30* amperes: the total reactance is then

$$x'_{s_2} = \frac{137}{30} = 4{\cdot}56\omega \text{ instead of } 4{\cdot}033\omega.$$

This augmentation of $4{\cdot}56 - 4{\cdot}033w = 0{\cdot}527\omega$, is due to the mutual induction between the end connections of these phases; the reactance of $1{\cdot}16\omega$ then becomes $1{\cdot}16 + 0{\cdot}527 = 1{\cdot}687\omega$, which corresponds to an augmentation of $\frac{1{\cdot}687}{1{\cdot}16} = 1{\cdot}45$. It is to be still further noticed that there is no magnetic attraction between the end connections of phases I. and III., but there is a considerable attraction between the coils of phase II. and those of the two other phases.

In addition, on three phase, the phases are no longer perfectly balanced on load; for a constant exciting current of 10 amperes the short-circuit current has been found to have the values given below.

1. *Three-phase.*
   Phase I.: $I_k = 35{\cdot}8$ amperes.
   Phase II.: $I_k = 31{\cdot}5$ amperes.
   Phase III.: $I_k = 36{\cdot}8$ amperes.

2. *Single-phase.—Two-phase in Series.*
   Phase I.–II: $I_k = 51{\cdot}25$ amperes.
   Phase II.–III.: $I_k = 51{\cdot}2$ amperes.
   Phase III.–I.: $I_k = 53{\cdot}5$ amperes.

3. *Single-phase—Per phase.*
   Phase I.: $I_k = 89{\cdot}5$ amperes.
   Phase II.: $I_k = 90{\cdot}5$ amperes.
   Phase III.: $I_k = 89{\cdot}5$ amperes.

The short-circuit test, single phase *per phase*, shows, as before, that without mutual induction the reactances of the three phases are perfectly *equal*.

HYDRO-ELECTRIC INSTALLATIONS OF SWEDEN.*

BY A. V. CLAYTON.

(*Concluded from page 54.*)

Summary.—After drawing attention to the characteristics of Sweden the author refers to the development of power transmission in that country. He then proceeds to describe typical installations, mentioning the features of particular interest.

Having digressed to describe briefly the subject of generators we will now return to Graninge. The current from the generators is led to the 5,000-volt 'bus-bar room for distribution to the outgoing lines of the 5,000-volt transmission and the primaries of the step-up transformers. This room is on the ground floor level, and in it are situated all the necessary transformers for the measuring instruments, the oil switches and connectors. All 'bus bars are laid in closed tunnels, and the only openings in these tunnels are at junctions to the 'bus bars. Further, it has also been arranged that the only insulators supporting the 'bus-bars are placed at these openings, so that they are easy of access for inspection, &c. The distance from the conductors to the walls of these tunnels is 6 in. for the 5,000-volt leads and 12 in. for the 40,000-volt. All the 'bus-bar connectors, instrument transformers, &c., are isolated and placed in respective fireproof cells. The switching apparatus is very simple: no fuses are used, oil switches with maximum relays taking their place. Between the generators and 5,000-volt 'bus bars there are maximum relay oil switches, and likewise the 5,000-volt outgoing line is provided with maximum relay oil switch. Each generator is provided with ammeter, voltmeter, wattmeter and synchronising apparatus. The 5,000-volt 'bus bars are in sections, so that the generators can be worked on separate sections or in parallel as required. Between the 5,000-volt 'bus bars and primaries of the step-up transformers there are no oil switches, but simply link connectors. The transformers are of single-phase type, of 720 kw. capacity each, and are used in sets of three to form complete 2,160 kw. three-phase transforming systems for each of the three generators. On the high-tension secondary side of the transformers are three-pole maximum relay oil switches for each set of transformers, and beside these there are connector links which permit of coupling any one of the transformers on to either of two sets of high-tension 40,000-volt 'bus bars. There are two outgoing transmission lines, each having its maximum relay oil switch, and they can be fed from either of these duplicate sets of 40,000-volt 'bus bars by means of connectors.

As is well known, great precautions must be taken against the effects of lightning discharges or over-tension due to other causes on aerial transmission lines of this kind, and the difficulties increase enormously when the transmission voltages get into high figures. Moreover, the very severe climatic conditions obtaining in Sweden, especially so far north as this power station is situated, call for special attention to this point. In the present case zinc roller tension limiters and horn lightning arresters are used, while powerful impedance coils are placed between these protective devices and the 40,000-volt 'bus bars. On each phase of the outgoing lines there are two horn arresters in series, one of which is connected in parallel with a water resistance. The water resistances consist of very large glazed earthenware bent pipes filled with water. The up-bent open ends of the pipes are covered with loose brass covers through which are brought conductors terminating in spiral wire ends immersed in the water. The horns and resistances of each phase are placed in separate chambers. It has been found that a gap of 32 mm. for the first horn and one of 40 mm. for the second horn, which is in parallel with the resistance, give the best results. Another means of preventing over-tension on transmission lines, and one which has proved exceedingly effective, is to make connections from the lines to earth through fixed resistances. The resistances are adjusted so as to allow a very small current constantly to flow to earth, and these connections to earth

* Abstract of a Paper read before the Institution of Electrical Engineers.

Digitized by Google

lead off the small static charges which would otherwise accumulate on the line. Experiments have been made with carbon and other classes of resistances for this purpose, but a circulating water resistance has proved the best.

Now as to the switchboard itself, which is placed on the first story over the 5,000-volt 'bus bar room. It is in the form of a circular sloping-top desk, while behind this desk are a number of cast-iron pillars on which are mounted the instruments corresponding to the switches on the panels of the desk switchboard. All the switches situated in different parts of the building are electrically controlled from the switchboard, as well as all rheostats and also the turbine gates, so that from this point the entire station is controlled. Signal lamps show whether the switches are closed or open. The board being of circular form permits an operator standing opposite to it to see all the instruments at once without running from one to the other, and, moreover, he has a full view of the entire station and the transformer cells, as there is a clear space to the machine house at the back of the instrument pillars. Each transformer is placed in its own little fireproof cell, the cells being in a row on the first story of the 40,000-volt building, on a level with and immediately opposite the

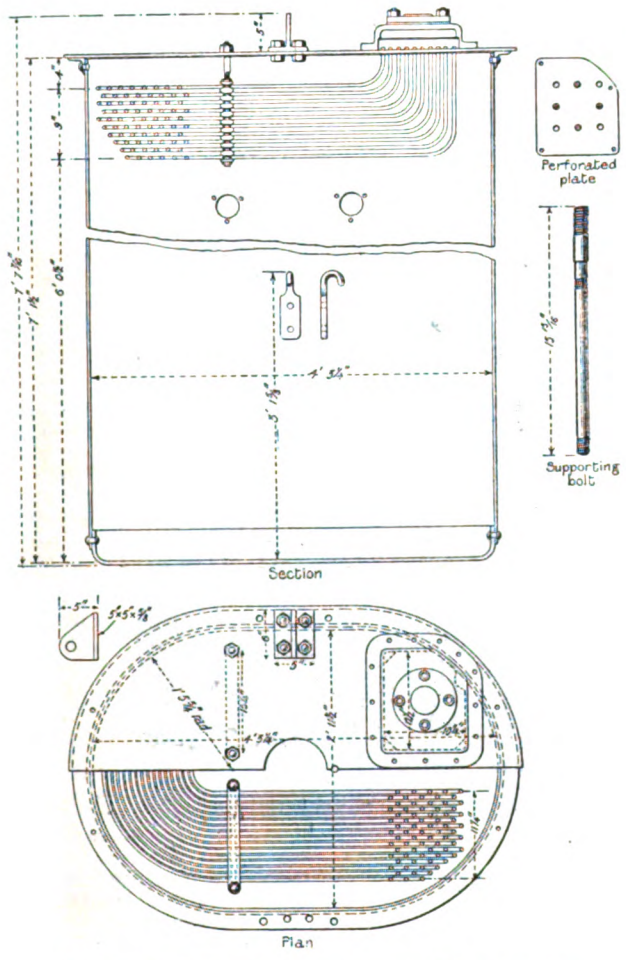

Fig. 5.—Box for Graninge 720 kw. Transformers.

switchboard alcove. The cells have fireproof iron doors front and back, the doors on one side opening to the machine hall and on the other to a long gallery having rails leading to a repair shop. The transformers stand on little trucks, so that any transformer can with the greatest ease be removed and replaced. The doors of the transformer cells on the machine hall side usually stand open, mainly with the object of seeing if the circulating water for the cooling coils is running properly. This can be observed from the machine hall and the switchboard alcove. There are signals to show if the temperature of any transformer rises too high, and in case of fire the iron doors of the cells can be instantly closed by operating a lever.

The cooling coils of the transformers may present some novelty, in that instead of having one or a few circulating pipes of large diameter, or a water jacket, they consist of a number of small diameter copper tubes placed in parallel, like a little water-tube boiler. Fig. 5 shows the box and cooling coils. In this construction the tubes are expanded or sweated into headers which form one side of distribution boxes for the inlet and discharge of the circulating water. The entire system of cooling tubes is placed at the top of the transformer box over the transformer itself, and is attached to the transformer box lid, so that when the lid is removed the coils are removed with it. By employing this construction an enormous cooling area can be got into a very small space, practically the only limit to the room required for the cooling coils being the amount of space which must of necessity be left between the tubes in order to obtain good circulation of the oil. Moreover, the cooling coils are at the top of the box, where the oil is hottest, and hence in the most effective and best position. A very complete arrangement is provided for tapping out the oil, boiling and refilling. It consists of a system of pipes to and from the transformers connected with oil-boiling tanks.

The use of oil-cooled transformers has only of recent years become general in Sweden. On account of the larger units now employed and the high voltages used for transmission, the use of oil-cooled transformers has become general. In the water-driven power stations it is, of course, easy to get water for cooling purposes, but in most sub-stations it would be a very troublesome job to have to arrange for circulating water, and hence in them oil-insulated transformers with ordinary air cooling must be used. As the sizes increased, extra radiation surface was obtained by casting ribs on to the outside of the boxes. As demands arose for still larger sizes, it was found that the oil would not transmit its heat quickly enough to the smooth inside circular box in order to get the full advantage of the increased area of the outside ribs. The suggestion of casting radiation ribs on the inside was a failure, the difficulties in casting being too great; and, in fact, even with ribs on the outside alone, the percentage of wasters in casting was very high. Therefore the next step was to make the walls or sides of the boxes with a very deeply corrugated section, in which case the area exposed to the oil inside and the air outside was practically the same. Even these boxes, when of great depth, were difficult to form and cast, and, therefore, they were cast in sections 20 in. deep and bolted together with a lead packing between. These sections were of fixed diameter and represented roughly the losses of a given size of transformer, so that with increased size a greater number of sections were added. Thus, for instance, a two-section box with top and bottom would be for a 100 kw. transformer, a three-section box for a 150 kw. transformer, and so on. These boxes, however, became very heavy and costly in larger sizes, and were abandoned in favour of boxes of wrought iron having similar deep corrugations. As in the case of the previously described water-cooled transformer boxes, the idea of keeping the radiation surface concentrated towards the top of the box where the oil is hottest has been carried out in these air-cooled boxes also. The small cistern seen in the illustration on the top of the box is provided to allow the extra space required by the oil when hot, on account of its expansion, and to keep a constant head of oil pressure against the lid of the box. This is necessary to prevent moisture condensing on the under side of the lid in cold weather, which happens if an air space be left between the top of the oil and the lid of the box. Such drops of moisture will fall through the oil on to the transformer, and may cause serious damage. The oil in this little cistern is connected to the main body of oil in the transformer box by a small tube, the upper end of which is some inches above the bottom of the little cistern, so that any moisture that may condense on the under side of the lid of the little cistern will not be drawn into the transformer box, but will lie at the bottom of the little cistern, and can periodically be drawn off from this through a pet-cock. The bottom of these boxes is circular and is of ¼ in. boiler plate, and the top part is corrugated and of 14 gauge sheets. Another idea of the heavy circular bottom is that it will stand pinching with crowbars and other rough handling in transport in places where proper lifting devices are lacking. In order to stop small leaks the whole box is galvanised after it is riveted and complete. The eventual successful commercial evolution of these boxes is in a large measure due to Mr. Alfred Fraser, of Messrs. John Fraser & Sons, Millwall, the makers of the boxes. It is remarkable what a difference there is in the radiation properties of cast-iron and wrought-iron surfaces.

As to the transmission line at Graninge, the greatest distance of transmission is about 40 English miles. There are, of course, much longer transmissions than this in service in Sweden—for instance, Hemsjo, 96 km., Yngredsfors-Varberg 90 km. It has even been suggested by the State engineer of the Trollhättan Falls to transmit power from there to Copenhagen, a distance of about 350 km., including 8 km. across the sea between Sweden and Denmark. The Graninge line consists of three single wires of 4·5 mm., about 0·18 in. diameter, carried on wooden poles. The pin of the top insulator is mounted on the wooden pole directly, while the two lower insulators are supported on an iron cross-bar. The insulators are of triple petticoat type, made in two pieces cemented together and supported on iron pins fixed to them by a tight packing of oakum between the pin and the inside of the insulator. Formerly it was customary to cement the insulator caps to the pins, the cement used

Digitized by Google

being mostly the litharge and glycerine mixture, but with this cementing it was found that the insulators split, owing to unequal expansion with the extremes of heat and cold pertaining to the Swedish climate. The wires are suspended in positions corresponding to the tips of an equilateral triangle, the distances between wires being 50 in. The distance of span between the poles is about 45 yds. generally, but at river crossings there are two spans of about 140 yds. each, and one at the estuary of nearly 400 yds. In the case of this latter span the conductors and their insulators are supported on triangular frames which are suspended from a steel hawser. The steel hawser passes over rollers on towers 120 ft. high, situated on the opposite shores, and is anchored to rocks at each end. Where transmission lines cross public highways or railways the law requires that such crossings shall be protected so that in the event of a conductor breaking the free end cannot fall down and thus be dangerous. This is effected by enclosing the transmission lines at these points inside a casing of iron lattice work supported on iron lattice poles situated each side of the crossing.

All the preceding power stations described are built with horizontal shaft turbines, and are typical of the most general run of power stations. In many cases, however, vertical shaft turbines and generators of the umbrella type are employed, principally on very low falls, where this type offers advantages. In these cases the turbines are placed in ordinary open flumes, over the top of which is the floor of the generating room, and the advantages are chiefly as regards variable levels of backwater in the tail race as well as cost. Fig. 6 shows the interior of a typical power station of this class. In the attempts made to get up high speeds on low falls quite freakish designs are sometimes met with. It may be remarked here that the Swedish practice in this respect is quite different from the American custom of employing gearing to increase the speed of generators driven from slow-speed turbines, in Sweden direct coupling being the rule.

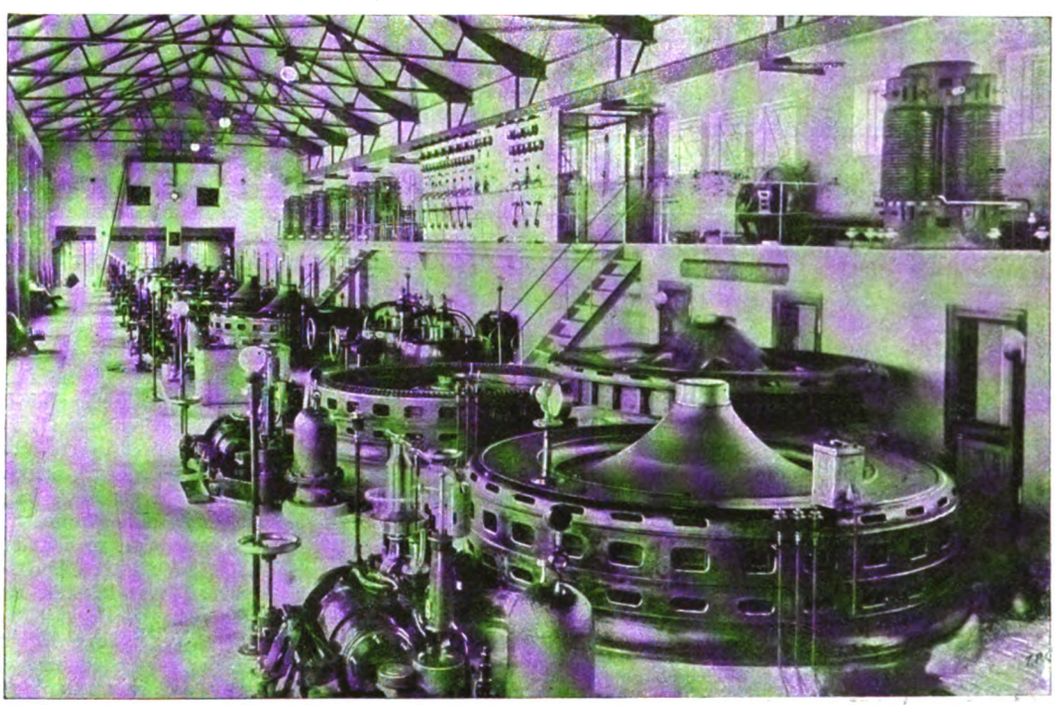

Fig. 6.—Interior of Power Station at Näs, Horndal, typical of the Vertical Shaft Turbine and Umbrella Type of Generator.

Another class of turbine generator set which is very interesting, and for which Mr. Böving has obtained patents, consists of two wheels running in opposite directions, the shaft of one being hollow and having inside it the shaft of the oppositely rotating turbine. To these two shafts are attached respectively the field and the inductor of the generator, both of which rotate, but in opposite directions. The result is that, for a given frequency and speed, the generator has only half the number of poles that would be required if the field alone rotated; in other words, it is equivalent to doubling the speed of the generator. Several of these have been at work at Hellefors for many years past, and are quite satisfactory. In vertical shaft turbines the rotating parts have, of course, to be suspended, and with the generator rotating field, the long and heavy vertical shaft, and the turbine wheels themselves, it will be seen that the weight to be supported is often very great. Many unsuccessful attempts were made to take up this weight on ball bearings, but now it is almost general to use hydraulic bearings, which float the entire system where the weight to be supported is too great to be taken up on the ordinary lignum vitæ turbine footstep. In a power station at Korsnäs no less than four pairs of turbines—that is, eight wheels—are used on one shaft. The fall in this case is only 6 ft., and despite the use of eight wheels, the speed is only 107 revs. per min., while the power is only 420 H.P. Installations with such very low falls utilising enormous quantities of water per horse-power developed are, of course, excessively costly compared with their power output. Twin wheels are, of course, the ideal; but in many cases quadruple wheels must be used to enable the use of large-size electrical generators at reasonably high speeds. Of course, on high falls the obverse obtains, and in such cases single wheels having high peripheral velocity are used in order to get reasonable speeds for the generators. A single-wheel turbine of this class, with an output of 3,300 H.P., is in operation on a 290 ft. fall at the works of the British Aluminium Co., at Stangfjorden, Norway. Even with this single wheel of large horse-power capacity the speed is 300 revs. per min., and at this speed the generators, which are of continuous-current type, had to be divided into two units of 1,100 kw. each.

On high falls, and even on only moderately high falls where pipe-lines are used, very great precautions must be taken against the dangers of water-hammer arising from the operation of the turbine gates with sudden variations of load. To protect against these, relief automatic by-pass valves are used. On still higher falls Pelton or impulse-type wheels must be used, but I do not know of anywhere in Sweden where wheels of this type are at work. There are, however, two installations being carried out in Norway where Pelton wheels are being used. One of these is at Tya, where a head of about 3,300 ft., probably the highest in the world, is utilised to develop about 70,000 H.P.; the other Pelton wheel power station is at Rjukanfos, also in Norway, where the head is about 1,000 ft. The units at the latter station will be of 14,500 H.P. each. It is interesting to note the low capitalisation cost of these latter big schemes. From calculations made by the Hydraulic Association of Scandinavia, the installation at Tya is estimated to cost about £525,000, or £7. 10s. per electrical horse-power developed. Where open intake water canals cannot be built—such, for instance, as on sloping ground—wooden pipe-lines are often used for the sake of cheapness. They are made of wooden planking about 3 in. or 4 in. thick, and bound at frequent intervals with strong iron hoops, the spacing between the hoops being dependent upon the pressure due to head of water in the pipes. These wooden pipe-lines cannot, of course, be used with advantage on anything but moderate heads, and they are often used for the first portion of a long, sloping pipe-line until the head gets too great.

DISCUSSION.

Mr. J. F. C. SNELL said he was very glad that such a Paper had been read, because they were an Institution of Electrical Engineers and not electricians, and therefore the adaptation of the great forces of Nature by means of hydro-electric plants, while not applicable in England to any great extent, must appeal to those who had to carry out work abroad. The author had given the price per electrical horse-power of some completed hydro-electric stations as £7. 10s.; that was practically £10 per kilowatt installed. He asked the author to amplify that figure and give the price that obtained in Scandinavia per horse-power-year or per kilowatt-year. The author had also stated that there were many cases in Sweden where the price of imported coal was so low as not to warrant the use of hydro-electric plant. The speaker thought it would be a very difficult matter for a steam-driven station to compete with a hydro-electric station installed at so low a capital outlay as £7. 10s. per horse-power, unless, of course, the added cost of transmission was unnecessarily high. He asked the author whether the 8 million horse-power which Sweden and Norway had between them was the horse-power calculated upon the drought rating, or whether it was taken upon the average rainfall for the year.

Mr. G. STJERNBERG said that although Sweden and Norway were lacking in coal they certainly made up for it in water power. He thought the author's figures for inherent regulation were very low and asked if the short-circuit current had been measured. He also questioned whether it was altogether a desirable thing with generators working on overhead lines to keep the regulation so low. With greater regulation the effect of short-circuits would certainly be much less severe. As to the statement in the Paper that no short-circuit troubles had been experienced in the Swedish power plants, he was told when travelling through the country that they had found it necessary in places to take special precautions against these troubles, choking coils without iron sometimes being inserted in the dynamo circuit. It was to be expected that some trouble of this sort would occur with machines of such high capacity. Referring to the transformer, he thought that the arrangement of the cooling ribs at the top of the transformer would probably give a good cooling effect, but one would think that such an arrangement would not tend to produce a good circulation of the oil in the transformer case. With such thin riveted wrought-iron sheets he thought it would hardly be possible to get the cases completely oil-tight.

Mr. H. BRAZIL asked the author whether the neutral point of the Graninge system was earthed.

Mr. CLAYTON stated that he believed it was not earthed.

Mr. BRAZIL, continuing, pointed out that that being the case the arrangement of the arrester horns described in the Paper was not very satisfactory, in that it required double the pressure to cause the horns to spark when the system was entirely insulated that it would when one pole was earthed. This was clear from the fact that when one pole was earthed only one horn was in circuit, but when all poles were insulated two horns were in series. Assuming that the horns were set for 50 per cent. rise, this would mean that each horn would spark across at 60,000 volts and that two in series would require approximately 120,000 volts, which was three times the normal pressure. With regard to the resistances used in connection with lightning arresters, these were very important, and it was generally agreed that a very large proportion of the troubles experienced with lightning arrester apparatus had been due to the resistance not being of sufficient capacity to withstand the heavy load thrown on them when a discharge occurred. The problem of designing a suitable resistance for the purpose was a peculiar one, in that it was required to have a very high ohmic value, and at the same time the capacity for absorbing very heavy loads for a short period. Having had considerable experience with the water and carbon type of resistance, he ventured to disagree with the author's conclusion that a water resistance was the best. He was quite prepared to agree with the author, if by carbon resistances he meant only the carbon rod or other compressed carbon type, but suggested that there were other types of carbon resistance, which were much to be preferred to the water type. The failures with the carbon rod type were nearly always due to the fact that it was very difficult to get the resistance per unit length anything like uniform, and when a number were in series it was more than likely that one of them had a high resistance point or crack in it. When a discharge occurred a very large proportion of the available potential was concentrated at this point; the rod got hot and broke and the whole resistance was useless. The remedy he suggested would appear to be rather paradoxical. It was to take the carbon rods and to break them into thousands of pieces, distributing these pieces in a suitably shaped groove. A resistance consisting mainly of bad contacts resulted. In this connection Mr. Brazil showed a resistance unit consisting of a fire clay slab 12 in. square by 1½ in. thick, with a zigzag groove ¾ in. deep and ⅝ in. wide moulded in it. In this groove was placed a special kind of carbon powder. The grooves were not parallel to one another, and a thickness of insulation at each point was provided which bore some relation to the potential between one leg and another at that point. As to the capabilities of this resistance, with the voltage of 6,000 across the terminals the current rose to a maximum of 1·9 amperes in just over two minutes and then slowly decreased to 1·35 amperes, at which figure it remained, even after eight minutes had elapsed. The maximum power absorbed in this case was 11·4 kw., and when steady 8·1 kw. With 10,000 volts across the terminals, the current rose to a maximum of 2·4 amperes, and then decreased to 1·8 amperes at the end of one minute when the resistance was switched off. The maximum load in this case was 24·2 kw. The above tests were, of course, very severe, and it was highly improbable that the resistance would be subjected to them in practice. The object in giving these figures was to show that even under the worst conditions the resistance would keep the current within safe limits. His objections to water resistances were: (1) They introduced moisture into the extra high-tension chamber; (2) they varied in resistance to a very great extent with the ordinary temperatures obtaining in sub-stations; (3) the possible range of temperature and therefore the capability of absorbing power for any length of time was very limited; (4) a very small quantity of impurity getting into the water would alter the resistance value to an enormous extent; (5) if subjected to severe cold they would freeze. Turning to the permanent leak arrester, he agreed with the author that this was a very valuable piece of apparatus, but imagined that it would require a good deal of attention, as the value of the resistance varied considerably, especially if anything got into the water. He believed that all engineers, if they could obtain a dry resistance which cost no more and was as efficient, would instal it in preference to the water type, and he suggested such a resistance similar to the one he had described. This resistance consisted of a number of insulating slabs made of material resembling porcelain with grooves about ¼ in. wide. These grooves were filled with a very high resistance powder, and the slabs were stacked one on top of the other and connected in series.

Mr. W. H. PATCHELL mentioned that it was unnecessary to go to Scandinavia to see the early forms of machinery and transmission apparatus mentioned in the Paper, as tilt hammers were used in this country, and flat-rod transmissions with wooden rods and also ropes were to be found working among the mines of Cornwall. The width at which the flat rods were kept apart depended simply upon the width of the water-wheel cranks. The author did not mention whether the water-jet earth resistances were turned on when a thunderstorm was seen approaching, or whether they were left on all the year round. Mr. Stjernberg had mentioned that the design of tank shown did not lead one to believe that the best circulation was obtained. If we had to go to Sweden to learn how to make transformers, it was gratifying to see that they had to come to England to see how to make the cases. He noticed the author mentioned that in the dynamos the pole-ring and the arms and boss were all cast in one piece, and the boss was not divided. He, the speaker, thought that it would be very difficult to get such a casting without the arms cracking.

Mr. A. V. CLAYTON, in reply, said that the £7. 10s. per horse-power referred to by Mr. Snell was not the electrical horse-power, but was the turbine horse-power. The price per horse-power-year obtained in Sweden was a very variable quantity. In some cases it was as low as 27s. 6d. per horse-power and in others amounted to as much as £6. 10s. On might take a fair average as 55s. per horse-power-year. In contracts which were made for a number of years at £6. 10s., the supply of the full power demanded was guaranteed; but where the supply was not guaranteed the price was at a lower rate. Mr. Snell accused him of making a statement that in many cases in Sweden the cost of imported coal was such that the cost of the hydro-power was unnecessarily high. He, the author, did not state in Sweden, or, at least, did not intend to. The 8 million horse-power available in Sweden and Norway had been arrived at on the average rainfall rating. In regard to Mr. Stjernberg's remark that the figures for the inherent regulation were very low, he had stated in the Paper that the figures were exceptional. In regard to introducing choking coils to check the flow of current on short-circuits, he thought that Mr. Stjernberg had been misinformed. Mr. Stjernberg had probably come across some isolated case, but it must not therefore be inferred that the practice was general. He might say he knew most of the power stations in Sweden, but he did not know of one where they had put in choking coils for that purpose. The circulation of the oil in the oil cooling boxes was a troublesome thing, but was overcome by the use of thin oils. Thin oils also gave better insulation resistance than thick oils. He agreed with Mr. Brazil's remarks re earthing. Of course, any dry resistance would be very much better than the water jets. Much experimenting had taken place, and carbon resistances had been discarded because of their inequalities. The protective devices were used in the summer when the lightning was about, and taken off during the winter. As to using a carbon resistance of that kind for an earthing device, that had also been tried, but the trouble was that damp sometimes got into the carbons and they cracked, and also the inequalities above referred to prevented their use. No doubt Mr. Brazil's broken carbon resistances were better than rod carbons. As to the question of casting the arms and the ring all in one piece, one would, of course, not attempt to do such a thing with iron. When steel was first cast it was exceedingly brittle, but in annealing the stresses were all removed. As to cradles at railway crossings, there was a feeling in Sweden that these were unnecessarily costly.

PATENTS IN 1909.

We give below an abstract of the twenty-seventh report of Mr. W. Temple-Franks, the Comptroller-General of Patents, which has been issued during the past few days. In the report it is mentioned that at the end of February, 1909, the Patent Office sustained a serious loss in the retirement from active service of the late Comptroller-General, Sir Cornelius Neale Dalton, K.C.M.G., C.B., who had held office since 1897.

After a brief survey of the history of legislation in regard to patents and designs and a discussion of the revocation of patents, the report proceeds to state that one of the outstanding features of the year 1909 was the enormous

Digitized by Google

development in aeronautics, the number of applications relating to this subject being more than three times the number received during the preceding year. The subject of locomotion in general, though continuing the slight falling-off noticeable during the past few years, still occupies the most prominent position in the field of inventive activity. The construction of motor-road vehicles has become so far standardised that the present tendency of inventors is to concentrate their attention mainly on the perfection of details. Applications dealing with wheels have slightly diminished, but this has been counterbalanced by the number of inventions relating to speed indicators and signals, due, no doubt, to the possibility that motor vehicles will in the future be required to give audible or visible warning of excessive speed. The interest shown by inventors in the development of the internal-combustion engine has been more than maintained. Following the tendency of last year, applications in connection with horse-drawn and railway vehicles show a slight decrease. Considerable attention has, however, been given to electric railway signalling systems in which the track rails are electrically continuous and are used for both the signalling and the power circuits. Inventions dealing with the mechanical handling of materials by conveyors and transporters are much in evidence, particularly in connection with the carrying of coal and ores from the working face to the bottom of the mine shaft. Problems relating to lighting have been a prolific source of invention, especially with regard to vapour or self-generating gas lamps and to means for automatically lighting and extinguishing street lamps.

The number of applications for patents during the year was 30,603, compared with 28,598 in 1908, and 28,915 in 1907. The number of specifications, provisional and absolute, shows an increase compared with those in 1908—viz., 21,553 and 18,705 in 1909, as against 19,495 and 17,746 respectively in 1908; but the number of patents sealed was only 15,065 compared with 16,284 in the previous year and 16,272 in 1907. The number of designs registered was the maximum recorded, viz., 25,754, compared with 24,389 in 1908, which latter was also a maximum figure. The number of trade marks registered was 6,112, compared with 5,965 last year and 6,255 in 1907.

The receipts from patents fees were £267,985, as compared with £262,890 in 1908, an increase of £5,095; from designs fees £5,578, as compared with £5,189, an increase of £389; and from trade marks fees £17,247, as compared with £17,358, a decrease of £111. The receipts from the sale of Patent Office publications were £12,029, as compared with £11,898, an increase of £131. The total receipts were £302,839, as compared with £297,335, an increase of £5,504. The total expenditure on behalf of the Office was £208,536, as compared with £179,531, an increase of £29,005. This increase is principally due to a payment of £30,000 in connection with the purchase of site for the new office buildings. The amount paid for salaries increased by £5,242, and the expenditure upon stationery, &c., decreased by £6,075. The total number of persons employed in the Office was increased during the year from 648 to 664. The number of readers who made use of the library was 157,235, as compared with 152,221 in 1908, an increase of 5,014 or 3·3 per cent., and the largest number recorded in any one year. The number of volumes added to the library was 5,858, of which 1,149 were volumes of patent specifications or journals (English and foreign) and 115 were trade catalogues. The remaining 4,594 volumes were text-books or periodical publications relating to scientific and technical subjects, and of these 3,384 were obtained by purchase and 1,210 by donation. The number of works in the library at the end of the year was 39,658, and the approximate number of volumes (exclusive of duplicates) was 124,000. A supplement to the author catalogue for the period 1898–1908 will be published early in the current year, with an appendix completing the work to December 31, 1909. It is proposed to print future supplements at much shorter intervals, thus making it possible to maintain a consolidated catalogue of the library in book form practically up to date. These supplements will be printed in an edition sufficient only for the library requirements, and will not be placed on sale or be available for public distribution. The new "relative" system of shelf classification of the library has been extended from B K to C R.

Through the courtesy of the heads of the Patent Offices in Germany and the United States, who have supplied for the purpose a duplicate set of their specifications, the systems of patent classification adopted in those countries are made as far as possible accessible to the readers in our library. The German classification comprises 89 classes, 480 sub-classes and 7,950 groups, and a list has been issued indicating the allotment under this system of all patents granted in Germany since 1877. One set of German specifications in the library is now being arranged in accordance with this classification, and 24 classes, comprising 2,547 groups, are already completed. A revision and extension of the United States classification has been in progress since 1905, and 90 classes and 7,863 sub-classes have been dealt with. Lists showing the allotment of specifications under this system are supplied by the American Patent Office and may be seen at the library.

The use of deposit accounts at the sale branch for the purchase of Patent Office publications continues to increase. During the year 32 new accounts were opened, and the total number of depositors is now 340, of whom 33 live in London, 115 in other parts of the United Kingdom and 192 abroad.

Patents.

The sum received from renewal fees was £154,777, as compared with £154,388 in 1908, an increase of £389; and that from sealing fees £15,220, as compared with £15,912, a decrease of £692.

The applications accompanied by provisional specifications, which fell off seriously in 1907 and slightly in 1908, increased by 2,058 in 1909. This increase brings the provisional specifications back to a higher point than they have attained since 1904. On the other hand, the applications accompanied by complete specifications, which decreased in 1908 by 244, decreased again, but only by 53. The falling off in these applications, which has never occurred before except in 1898, appears now to be checked, the number filed during the last six months being very considerably in excess of those filed in the corresponding months a year ago. The applications received from women inventors numbered 648, as compared with 572 in 1908.

There were 1,509 applications made by way of communication from abroad; of which 731 came from the United States of America, 431 from Germany, 54 from France, 42 from Canada, 30 from Switzerland and 28 from Austria-Hungary. An appendix shows the number of applications made in this country under the provisions of the International Convention for the Protection of Industrial Property by the various States of the Union during each of the last five years. The total number of such applications in 1909 was 2,303.

The cases where a complete specification is reported as wholly anticipated or not anticipated at all are decreasing in number year by year, while those where it is reported as partially anticipated are increasing. It also appears that there is a growing tendency to meet the reported anticipation by an amendment of the specification, and a consequent decline in the number of cases in which a reference to a previous specification is inserted. The number of such references inserted in the specifications of 1908 was only 310, as against 426 and 523 in those of 1907 and 1906 respectively. There was a large increase in the number of applications received in 1909 from England and Wales, a slight increase in those from Scotland, and a decrease in those from Ireland. The applications from most of the British Colonies are about equal in number to those made in 1908, but those from Canada show a large increase. There is a decrease in the number of applications received from Austria, Belgium, Denmark, France, Germany, Holland, Italy and Spain; and an increase in those from Russia and the United States.

An appendix shows the number of patents granted in 1908 in the United Kingdom, the United States, Germany, Austria-Hungary and Switzerland to persons resident within and outside the country. The percentage of patents granted to persons resident outside the country was: For the United Kingdom 46·2, United States 10·1, Germany 32·4, Austria-Hungary 71·2 and Switzerland 64·0. The number of applications made for the restoration of patents which had lapsed in consequence of the non-payment of renewal fees was 31, of which 3 were subsequently withdrawn and 7 are still pending. There were 22 hearings in connection with these applications, and in 21 cases the patent was restored.

Under the provisions of sec. 26, which empowers the Comptroller to revoke a patent upon the application, within two years from the date of the patent, of any person who would have been entitled to oppose its grant there were 9 applications, but 1 of these was subsequently withdrawn and 3 are still pending. In 2 of the 5 decided cases the patent was revoked, in 2 an amendment of the specification was required, and in 1 the application was dismissed. There were 2 cases in which patentees availed themselves of the provisions of sec. 26 (3) and offered to surrender their patents. In 1 of these cases the patent was revoked and the other case was not proceeded with. The number of applications made for the revocation of patents worked exclusively or mainly outside the United Kingdom was 55, but 27 of these were subsequently abandoned. In 11 of the remaining cases the patent was revoked, in 5 the application was dismissed, in 1 the patent expired after proceedings had been begun, and 11 cases are still pending.

During the last 10 years the number of hearings upon oppositions to the grant of patents was 1,304, and the number of appeals to the law officer in these oppositions 254, of which 43 were withdrawn or abandoned and 32 are still outstanding, while in 1 case the application for the patent was abandoned. The number of appeals heard by the law officer in these cases was, therefore, 178. In 103 of these appeals the decision of the Comptroller was supported, in 52 varied and in 23 reversed.

Nine petitions, 5 relating to patents of the year 1896, 3 to patents of the year 1895 and 1 to a patent of the year 1888, which had previously been extended for seven years, were lodged during 1909. Of these, 5 were abandoned and 2 dismissed and 2 cases are still undecided. There are now 4 patents in force which have been prolonged beyond the normal period of 14 years, viz., Nos. 8,700 of 1892, 10,274 of 1894, 1,272 of 1894 and 17,112 of 1894.

The names of 9 patent agents were added to the register during the year, the total number on the register on December 31st being 265.

Designs.

The number of designs applied for during the year was 24,816, exclusive of 1,596 sets of designs, as compared with 23,867 single designs and 1,040 sets in 1918. The number of designs refused registration, on account of their similarity to designs already registered, was 821. During the year 1,050 applications for registration of designs (including the above-mentioned 821) were objected to by the Comptroller. The objections, other than those on account of similarity to designs already registered, were chiefly on account of want of subject matter or want of substantial novelty. The number of applications made for the cancellation of registration on the ground that the design was used for manufacture exclusively or mainly outside the United Kingdom was 25, and in 24 cases the registration was cancelled, 1 being abandoned. The number of designs of which the copyright was extended at the end of five years for a further period of five years was 877, or 3·9 per cent., as compared with 938, or 4·6 per cent. in 1908.

Trade Marks.

The number of applications in 1909 for the registration of trade marks (including 173 applications made to the Cutlers' Company of Sheffield)

Digitized by Google

was 10,880, as compared with 10,645 in 1908. The receipts from various sources on account of trade marks amounted to £17,246. 11s. 4d., including the sum of £2,546. 15s. for renewal fees. The notices of opposition to the registration of trade marks numbered 254, and the cases of opposition heard under sec. 14 of the Act 44.

A number of appendices are attached to the report, and give in tabular form the particulars referred to in the report.

METHOD OF TESTING THE MECHANICAL STRENGTH OF METALLIC FILAMENTS.*

BY T. MÜLLER.

Lamps intended for use in trains and in places where they are exposed to unusual vibration require to be capable of resisting considerable shocks. A method of testing lamps for this property has been in use for the last six months in the laboratory of the telegraph department of the Swiss railways at Berne, and a description is given in the present article of the system employed.

The shocks to which the lamps are exposed are produced by a rubber ball, filled with lead, which is allowed to roll down an inclined plane and to impinge on the bulb of the lamp at the bottom. The ball weighs 120 grammes—*i.e.*, rather more than 4 oz. The inclined plane is graduated in centimetres throughout its length, and has an inclination of 10 per cent. The lamp under test is suspended by flexible cord at the bottom of the inclined plane. The ball is first started from a distance of 20 cm. from the lamp. If this shock is successfully resisted, the distance is increased by steps of 5 cm. until the filament breaks. The distance traversed by the ball when breakage occurs is taken as a measure of the power of the filament to resist shock and vibration.

The figures obtained under test are given in the following table, the different letters denoting the various makes.

Maker's reference number.	Volts and c.p. frosted on bulb.	Actual Hefner c.p.	Watts per Hefner c.p.	Length of path in cm.
A	125 25	25·5	1·18	30
	125/25	25·0	1·21	40
	125/32	34·0	1·18	50
	130/25	25·7	1·22	25
	130,25	25·7	1·22	25
	130/32	32·6	1·20	20
			Average=1·20	36
B	125/25	24·3	1·39	40
	125/32	30·7	1·26	35
	130,25	25·0	1·35	35
	130,32	31·5	1·30	35
			Average=13·2	36
C	125/25	26·4	1·17	35
	125/32	31·0	1·13	30
	130/25	22·0	1·30	45
	130/32	31·8	1·15	40
			Average=1·19	37·5
D	125/25	25·2	1·31	40
	125/32	31·8	1·19	40
	130/25	26·4	1·23	45
	130/32	32·4	1·20	40
			Average=1·23	41
E	125/25	...	...	80
	125/25	...	...	45
	125/32	...	...	35
	125/32	...	...	30
	130/25	...	...	40
	130/32	...	...	25
			Average=1·20	42·5

Other results given include a group by one maker giving 53 as an average, and five groups by another maker giving averages of 57, 90, 47·5, 32·5 and 25, the last being for two 155 volt-32 c.p. lamps.

The following general conclusions may be drawn: (1) The figure denoting the mechanical strength varies considerably with the different makes. (2) There is no traceable connection between mechanical strength and electrical efficiency. (3) For a given voltage the strength appears to be greater the lower the candle-power, and for lamps of a given candle-power the strength is greater the lower the voltage. (4) The filament itself is not always the most fragile part seeing that several of the breakages took place in the supporting glass rod or at the hooks or contacts.

The length of the turns composing the filament has a direct bearing on the results, which might in some cases be better if the length composing one turn were reduced. Curiously enough, those lamps which had the highest efficiency had also the greatest mechanical strength on an average. Blows caused by allowing the ball to traverse a distance of 80 cm. are very heavy, and lamps which survive till this stage may be considered to be thoroughly well made. When the lamps are alight it is not at all easy to break them. A succession of heavy blows tends to knock the filament out of shape and to bring the convolutions in contact with one another. Probably it would be a good plan to clean the lamps, shades, &c., while the lamps are alight.

* Translated (and slightly abbreviated) from the "Elektrotechnische Zeitschrift."

THE ELECTRIC COMMERCIAL VEHICLE AT THE CLOSE OF 1909.*

BY J. H. VAIL.

In the business progress of electric vehicles, the year 1909 has witnessed a distinct advance. The more progressive central stations recognise the growing value of this new field for selling energy, the importance of which was previously unsuspected.

At the close of 1908 there were five central stations using electric vehicles in their daily operations. Compared with this we find, at the close of 1909, central stations in the following cities have adopted these vehicles: New York, Brooklyn, Philadelphia, Boston, Rochester, Buffalo, Cleveland, Atlantic City, Chicago, Des Moines, New Bedford, Cedar Rapids, Davenport, St. Louis, Rio Janeiro. There can be no doubt of the awakened interest on the part of progressive business concerns in those cities where the electric light company takes the lead. The annual income to electric lighting companies from charging electric vehicles now ranges from £100 to £10,000 per year. The kilowatt-hours of electrical energy sold by meter for charging electric vehicles by one company active in this field of enterprise, in a city of less than 300,000 population, were as follows: In 1906 the average monthly consumption was 23,828 kw.-hours, and in 1909 the average monthly consumption was 46,720 kw.-hours, exclusive of energy used for the company's own vehicle service.

It is an important fact recognised by all that this revenue is profitable in a larger degree than any other service supplied, for two leading reasons. First, the income is derived during hours of minimum demand that were hitherto unprofitable. Second, no company has been obliged to invest any new money in station equipment to serve this class of business.

Of the total number of commercial electric vehicles in use, the General Vehicle Co. has manufactured upwards of 1,600. The salient points of the vehicles made by this company are the one-motor drive, roller bearings, enlarged battery capacity and a conservative rating.

It is recognised that the large adoption of the electric commercial vehicle must come through the education of the central station manager up to the value of the vehicle as a revenue producer, and of the business men up to the advantages in reliability, economy and utility. The whole matter is not one of sentiment, but a proposition of dollars earned by enterprising progress. The following are examples of what is being done in America. The Whites Express Co., of Brooklyn, operates four 2-ton trucks, and six 3½ ton trucks. These make as high as 250 delivery stops per truck in daily trips of from 35 to 50 miles. The estimated supply of electrical energy is from 85,000 to 100,000 kw. hours per year. The Motor Delivery Co., as mail contractors in New York City, operates 16 electric wagons of 1,000 lb., 2,000 lb., 4,000 lb. and 7,000 lb. load capacity, and quite recently at holiday times several extra machines were impressed into service. The quantity of mail hauled, the promptness of delivery, and the aggregate excellence of the electric mail service exceeded all previous experience of the New York City post office.

Department stores and others find they can rely on making from 100 to 200 delivery stops per wagon in circuits of 40 to 50 miles, on a single charge of battery. The amount of energy for a full battery charge for a 1,000 lb. wagon is 19 kw.-hours, and for a 2,000 lb. wagon, 23 kw.-hours. Many prominent brewers have demonstrated the economic advantages of electric delivery service. Early orders of 1902 and 1903 have been followed by repeat orders from year to year, so that many of the brewery equipments comprise the early and also the most recent types of vehicles. The 3½ ton and 5½ ton trucks are used for a great variety of heavy trucking. The amount of energy for a full battery charge for the 3½ ton truck is 39 kw.-hours, and for the 5-ton truck 47 kw.-hours.

The Rates for Subscriptions to "THE ELECTRICIAN" are as under :—

	Year.	Half-Year.	Quarter.	
United Kingdom .	26s. 0d.	13s. 6d.	7s. 0d.	Post free.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New Volumes of "THE ELECTRICIAN" *commence in April and October.*
(This charge includes all Supplements.)
Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. B. Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-eighth issue of the Supplement is published (Gratis) with the current number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPEOIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,086 pages), bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

PATENTS DURING 1909.

The chief interest of the Annual Report of the Comptroller of the Patent Office at the present time is the view it affords of the effect produced by the Patents Act of 1907. The result of such a measure takes some time to be fully apparent, and we must be content to wait, probably for another three or four years, before the merits or demerits of this Act can be judged at their full value. In this connection we refer more particularly to the question of revocation, which was the most drastic of the alterations then introduced, though, as pointed out by the Comptroller, the principle involved was not really novel. Up to 1907 it appears that the form of Letters Patent granted by the Crown contained a clause providing that the patent should be void if it should be made to appear to the King, or to any six or more members of the Privy Council, that the grant was prejudicial or inconvenient to the King's subjects. Under this clause Letters Patent might always have been determined or declared void, and by the Act of 1902 power was expressly given to the Judicial Committee of the Privy Council to revoke a patent worked mainly or exclusively abroad if the reasonable requirements of the public in the invention were not satisfied in this country. The Comptroller points out that the provisions of this section of the new Act are not so stringent as those in force in many countries, as for example, Germany and Canada. In

Digitized by Google

both these countries the obligation to work a patent after a definite period is directly enforced, and the jurisdiction of the Court is not dependent, as in this country, on proof of the fact that the patented article is manufactured, or the process carried on, mainly or exclusively outside the United Kingdom.

It is now becoming more clear what may be expected in regard to the revocation of patents in this country; and the requirements are becoming more defined. The applicant for a revocation must give some *prima facie* evidence that the article is mainly or exclusively manufactured abroad. For this purpose the whole foreign manufacture is considered, and something more than a mere percentage below one-half of the total manufacture must be shown. The tribunal has to decide whether the working is adequate under the circumstances, and whether the article is manufactured in the United Kingdom to as great an extent as can reasonably be expected, having regard to the industrial developments in other countries. It appears that the main point to be decided is whether there has been a reasonably honest effort on the part of the patentee to manufacture in this country or to grant licences on reasonable terms; or whether, on the contrary, the patentee has abused the privileges and the monopoly granted to him, either by showing an undue and unjust preference to foreign countries, or by the imposition of unreasonable prices or unreasonable terms, or by wholly neglecting this country in his efforts to develop foreign trade. Evidently there is much to be taken into account in arriving at a decision, for there are many circumstances—such as date of the patent, the need of the invention, the demand for the article or process, the state of the art, and the stage of progress at which the invention has arrived—that all have a bearing on each particular case.

It will be admitted that revocation is a serious step, and that it materially affects the value of the protection afforded by patents in this country unless such revocation is obtainable only on very adequate grounds. We think it will be allowed that every care is being taken. From the records so far available it appears that revocation has not been made too easy; and, no doubt, this is the correct attitude for an institution such as our Patent Office to maintain. Up to December 31st last there have been 73 applications, but only 17 of these have been successful.

As to the indirect effects of the Act, it is also a little difficult to judge. It has become apparent that, if the patentee does not himself manufacture, orders have been given to British firms and licences have been offered for the manufacture of the article or carrying on the process in order to meet the requirements of the Act. There cannot be much doubt, therefore, that the existence of the section and of the power to revoke a patent has brought about the establishment of factories in this country and has led to the increased employment of British labour. There has been some fear that the Act might have a bad effect on the applications for patents from abroad. Possibly there may be a slight falling off, but we doubt if the effect of the Act can be traced in this way at present, as comparatively large fluctuations occur from year to year. All that can be said with certainty is that the number of applications during the past year was the highest number but one on record.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Anlasser und Regler für Elektrische Motoren und Generatoren. By RUDOLF KRAUSE. 2nd edition. (Berlin: Julius Springer.) Pp. xi. + 149. M.5.

The theory, construction and methods of connection of motor starting and regulating rheostats and dynamo field regulators are ably expounded in the present volume. The subject is an important one. The author deals with it authoritatively and clearly, and has included a vast amount of useful information in the 15 chapters comprising the work. The present edition has been improved; not only has it been enlarged, revised and brought up-to-date, but it has been partially rearranged, and a special chapter has been added containing fully worked out numerical examples, which readily show the practical application of the mathematical formulæ involved. This chapter adds considerably to the merit of the book, which contains a large number of excellent diagrams.

Starting with a few introductory notes on the functions of starting and regulating rheostats and on the different types, the method of determining the size of the resistance material for transient and permanent working is given in Chapter I. Chapter II. contains some brief remarks on the permissible loading of switch contacts, and on spark prevention (magnetic blow outs, &c.). The method of arranging the resistance material is discussed in Chapter III., and in Chapter IV. the fundamental connections of hand-operated starters are explained for series, shunt, compound-wound and three-phase motors, and for reversing motor switches. Various designs of hand-operated starters with special devices to protect them from overload, loss of voltage, too rapid starting, &c., are given in Chapter V., and automatic self-starting rheostats are considered in some detail in the following chapter.

The speed regulation of motors is explained in Chapter VII., which is followed by a short one on motor braking by the aid of starters and resistances. Controllers are very well dealt with in Chapter IX., and the general characteristics of dynamo field regulators for direct and alternating current are set forth in Chapter X.

The mathematical formulæ for calculating the grading of motor starters and regulators are deduced in Chapters XI. and XIII., respectively, their graphical determination being given in Chapter XII. The mathematical and graphical methods applicable to generator field regulators are similarly given in Chapter XIV. These chapters are excellent and are deserving of close study. The graphical solutions are especially noteworthy. Finally the practical application of the preceding methods is explained by the aid of no fewer than eight complete examples in Chapter XV.

Elementary Treatise on Electricity and Magnetism. By G. CAREY FOSTER and ALFRED W. PORTER. 3rd edition. (London: Longmans, Green & Co.) Pp. xix. + 623. 10s. 6d. nett.

This third edition of a work which must now be known to the majority of serious students of electricity shows the sound knowledge and the progressive spirit that are to be expected from the authors responsible for its present form. The treatise under review is, in a sense, elementary; but the majority of students would rightly consider their knowledge to be of an advanced character if they had assimilated all its contents.

The book occupies an almost unique position in the fact that there is no lack of continuity or completeness in the theory; and yet scattered through the work there are numerous references to apparatus and experiments, well illustrated with diagrams. These references are not such as appeal specially to the electrical engineer; but are such as give life and body to the theory. Students who are familiar with the previous edition will be glad to know that the numbering of the old articles has been unaltered, and that where new articles have been added their presence has been indicated by asterisks. Thus a glance through the table of contents shows what new matter has been added. In the chapter on electrical capacity and condensers there are new articles on Kerr's electro-optic

Digitized by Google

effect, and on pyro-electricity. In the chapter on thermo-electricity there is a new article which contains a neat treatment of a circuit of three metals in series. In one of the chapters on electromagnetic induction there are new articles on the magnetic field associated with electric convection, and on the energy of a moving charge; and the way is prepared for the very interesting last chapter on *recent developments*. Students who have attempted to follow modern work will be delighted with the last chapter, which deals with phenomena which have either been recently discovered or have recently come into prominence. This chapter is only 30 pages in length, and yet it manages to cover an enormous area with considerable success. There are articles on cathode rays, which the authors very properly prefer to call cathode streams; these articles enable the reader to be introduced to the notion of streams of negatively charged particles. A consideration of Röntgen rays caused by the impact of the streams against an obstacle naturally follows. Becquerel rays are next described, and they prepare the way for the study of radio-activity. Succeeding articles deal with the Zeeman effect, canal rays, and electrons. The chapter concludes with applications of the electronic theory to explanations of the electrical and thermal conductivity of metals, of thermo-electricity, and of certain magnetic effects.

At the end of the book there are some tables which were not in the second edition; and, altogether, the current edition contains about seventy pages more than its predecessor.

Storage Batteries: Their Theory, Construction and Use. By A. E. Watson. (Lynn, U.S.A.: Buliver Publishing Co.) Pp. vi. —135.

This is an excellent little book, written almost entirely from the purely practical point of view; indeed, it may be said that the "theory" extends very little beyond the title. After describing the general action and construction of batteries, detailed instructions are given for making a battery, the information given being eminently suitable for the amateur. The book concludes with a description of commercial cells used in America, and typical installations. Switchboard diagrams and brief particulars of boosters are also included.

Making Wireless Outfits. By Newton Harrison. (London: E. & F. N. Spon.) Pp. 61. 1s. 6d. net.

Wireless Telephone Construction. By Newton Harrison. (London: E. & F. N. Spon.) Pp. 41. 1s. 6d. net.

These two little books have been written for the benefit of those amateurs who wish to build up their own apparatus. Careful directions are given, in comparatively non-technical language, for the construction and erection of small wireless outfits, which, if followed, should lead to successful results; at any rate so far as spark telegraphy is concerned. With wireless telephony the difficulties are much greater; the arc is very troublesome, and the novice must be prepared for many failures.

CALCULATION OF THE OVERHANG LEAKAGE IN THREE-PHASE MOTORS.*

BY DR. M. KLOSS.

Summary.—In the present article it is shown how the leakage of the coil ends of an induction motor or alternator can be found in a simple manner.

For determining the circle diagram of a three-phase induction motor two quantities are required—the magnetising current i_μ and the ideal short-circuit current i_k. The magnetising current produces the ampere-turns in the stator winding necessary to drive the normal flux along the main magnetic circuit. The short-circuit current produces the ampere-turns required to drive the normal flux (assuming constant applied E.M.F.) along the leakage path. The relation between the flux and the ampere-turns is given by

$$\Phi = 0{\cdot}4\pi \,.\, AT \,.\, \Delta, \quad \ldots\ldots\ldots \quad (1)$$

where Δ denotes the permeance of the path of the flux produced by AT. At short-circuit, with q slots per pole and phase and z conductors in series per slot, this becomes

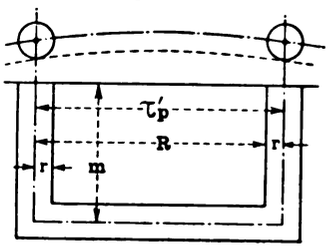
$$\Phi = 0{\cdot}4\pi q z i_k \sqrt{2}\cdot 2(\Delta_n + \Delta_z + \Delta_e), \quad \ldots\ldots \quad (2)$$

where Δ_n = permeance of slot leakage path,
Δ_z = permeance of zig-zag leakage path,
Δ_e = permeance of overhang or coil-end leakage path,
all with respect to one coil side.

The first two quantities are easily calculated according to well-known formulæ (*e.g.*, those due to Arnold). The last is not so simple and forms the subject of the present article.

When the overhang of a three-phase motor is considered, with its various shaped bent and straight coils, and an attempt is made to depict the field due to the action of the three phases, it would at first appear that the problem is insoluble. To simplify the procedure, therefore, various assumptions are necessary, but in making these we must keep quite clear the way in which these assumptions affect the result, and in any case we must avoid too large an estimation of the short-circuit current; in other words, the leakage must not be underrated.

Assumptions for Simplifying the Calculation.—Consider first a straight coil made up of three slots per pole and phase ($q = 3$), without regarding the action of the other phases. We first assume that these q coils are all combined in one circular coil whose section equals the sum of the q individual sections. Further, we shall assume the corners to be rectangular and not round as in practice. The lines of force are also taken as circular. The equivalent rectangular coil-end is shown in Fig. 1.



Coil Head and the Equivalent Right Angle.

Permeability for a Circular Section carrying Current.—There are two parts to be considered—the internal and the external. For the internal it is shown that the specific permeance (*i.e.*, the permeance per centimetre length) is

$$\lambda_i = 0{\cdot}04. \quad \ldots\ldots\ldots \quad (3)$$

For the part outside the circular section of conductors we get per centimetre length

$$\lambda_a = 0{\cdot}367 \log \frac{R}{r}. \quad \ldots\ldots\ldots \quad (4)$$

Hence the permeance of a coil-end—neglecting the effect of the other phases—will be

$$\Delta = \left(0{\cdot}04 + 0{\cdot}367 \log \frac{R}{r}\right) 2m + \left(0{\cdot}04 + 0{\cdot}367 \log \frac{m}{r}\right) \tau'_p. \quad (5)$$

The Permeance of the Overhang of a Normal Three-phase Winding.—Before simplifying the above formula the effect of the other phases will be considered. Instead of $\log R/r$ in equation (4) there will be a summation corresponding to $\Phi_I + \Phi_{II} + \Phi_{III}$, and we get for the *axial* part

$$\lambda_a = 0{\cdot}367 \left\{ \log \frac{R}{r} + \tfrac{1}{2} \log \frac{2\frac{R}{r} - 1}{\frac{R}{r} - 2} + \tfrac{1}{2} \log \frac{3\frac{R}{r}}{\frac{R}{r} + 4} \right\} \quad \ldots \quad (6)$$

To take the *tangential* part into account, the term for this has to be multiplied by 0·94.

Hence, instead of equation (5), the following expression is obtained:—

$$\Delta_e = \left\{ 0{\cdot}04 + 0{\cdot}367 \left(\log \frac{R}{r} + \tfrac{1}{2} \log \frac{2\frac{R}{r} - 1}{\frac{R}{r} - 2} + \tfrac{1}{2} \log \frac{3\frac{R}{r}}{\frac{R}{r} + 4} \right) \right\} 2m$$
$$+ 0{\cdot}94 \left(0{\cdot}04 + 0{\cdot}367 \log \frac{m}{r}\right) \tau'_p. \quad \ldots \quad (7)$$

To simplify this formula we must see what values r and R/r assume in practice. From a large number of actual motors it was found that, with close approximation,

$$r = 0{\cdot}5\,\text{cm.} + 0{\cdot}052\tau'_p \quad \ldots\ldots\ldots \quad (8)$$

and

$$\frac{R}{r} = 10 + 0{\cdot}1\tau'_p \quad \ldots\ldots\ldots \quad (9)$$

* Abstract of an article in the "Electrotechnik und Maschinenbau."

Digitized by Google

Substituting in equation (7) we then get

$$\Delta_s = \left\{0{\cdot}04 + 0{\cdot}367\left[\log(10 + 0{\cdot}1\tau'_p) + \tfrac{1}{2}\log\frac{19 + 0{\cdot}2\tau'_p}{8 + 0{\cdot}1\tau'_p} + \tfrac{1}{2}\log\frac{30 + 0{\cdot}3\tau'_p}{14 + 0{\cdot}1\tau'_p}\right]\right\} 2m + \left\{0{\cdot}038 + 0{\cdot}345\log\frac{m}{0{\cdot}5 + 0{\cdot}052\tau'_p}\right\}\tau'_p \quad . \quad . \quad . \quad . \quad . \quad (10)$$

which gives us Δ_s in terms of m and τ'_p. Curves were then drawn giving Δ_s as a function of τ'_p for different values of m, such as occur in practice. From these curves—which were practically straight lines—it was possible to replace equation 10 by the much simpler form

$$\Delta_s = 1{\cdot}41(m-1) + 0{\cdot}24\tau'_p. \quad . \quad . \quad . \quad . \quad . \quad (11)$$

Taking now the usual method of expressing the length of a mean turn, viz., $lm = 2(L + \tau'_p + A)$, where L = active core length, τ'_p the pole-pitch at centre of slots and A an increment chiefly dependent on the pressure, we have the following simple empirical relation:—

$$m = 1{\cdot}0 + 0{\cdot}05A + 0{\cdot}04\tau'_p$$

which, inserted in equation (11), gives

$$\begin{aligned}\Delta_s &= 1{\cdot}41(0{\cdot}5A + 0{\cdot}04\tau'_p) + 0{\cdot}24\tau'_p \\ &= 0{\cdot}705A + 0{\cdot}296\tau'_p \\ &\simeq 0{\cdot}7A + 0{\cdot}3\tau'_p, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)\end{aligned}$$

or, if l_s = mean length of overhang, we can write

$$\Delta_s = 0{\cdot}7l_s - 0{\cdot}4\tau'_p, \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

Split-phase Winding.—For a split-phase winding (overhang in three planes) this formula becomes

$$\Delta_s = 0{\cdot}65A + 0{\cdot}2\tau'_p \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

or,

$$= 0{\cdot}65l_s - 0{\cdot}24\tau'_p, \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

where $A = l_s - \frac{4}{8}\tau'_p$.

The above formulæ hold for motors with slip-ring armatures and for short-circuited armatures where the rings are close to the core, for in these cases the effect of the rotor overhang on the leakage can be neglected.

In squirrel-cage rotors, where the rings lie some distance away from the rotor, or in wound rotors where the rotor winding is very close to that of the stator, the coefficients in the above formulæ must be reduced by some 10 to 20 per cent.

Having determined the overhang leakage in the above manner and also the slot and zig-zag leakage, the ideal short-circuit current can be found at once from the expression

$$i_k = \frac{\Phi}{0{\cdot}4\pi q z \sqrt{2}(\Delta_s + \Delta_z + \Delta_s)},$$

where Φ is the main flux of the motor.

It only remains to mention in what way the calculation of the overhang leakage is affected by the assumptions introduced at the commencement. First, with respect to taking all the conductors in the overhang as forming one circular bar, this gives the leakage on the high side, for it assumes all conductors to be equally effective, which is not the case actually. Then, again, no distinction has been made between bent and straight coils. Now the surface enclosed by one of the former is larger than that enclosed by one of the latter, hence calculating the leakage for a straight coil also tends to make it too large. A partial offset to the above is due to the effect of the contiguity of the shield bearing, which tends to increase the leakage path. In practice, however, the above simple formula—free from all logarithmic terms—is found quite near enough.

SWITCH AND TRANSFORMER OILS.

The following is an abstract of the discussion which took place at the meeting of the Manchester local section of the Institution of Electrical Engineers when Messrs. W. Pollard Digby and D. B. Mellis read their Paper on this subject. An abstract of this Paper appeared in our issue of April 1st.

DISCUSSION.

Mr. C. J. Beaver (Messrs. W. T. Glover & Co.) referred to several points. The first was the general character of the oils which had been taken by the authors as typical samples of switch and transformer oils. If the oils were arranged in order of merit so far as the electrical and chemical properties were concerned, and in order of magnitude so far as the physical figures were concerned, several features became noticeable. For instance, there was a rough relation between the specific resistances and breakdown voltages and between breakdown voltages and alkalinity or acidity, though not between breakdown voltages and resinoid contents. It was also noticeable that no relation existed between the physical and electrical properties, H3 and H being the best of the series and almost equally good electrically, but being comparatively wide apart physically. While some relation was to be expected between specific resistance and dielectric strength, and also between dielectric strength and purity, he did not think the impurities indicated in the table accounted for the wide difference between the various oils in specific resistance and dielectric strength. His experience was that alkaline, acid and resinoid substances were not the most usual kinds of impurity met with in mineral oil, but that moisture was by far the most predominant source of variation in electrical properties. It was practically impossible to dry an oil perfectly by the application of heat, and it was certain that the elimination of the last traces of moisture from an oil would make far more difference to its electrical properties than would alkaline, acid or resinous substances, such as were referred to in the table. In connection with the question of moisture, he thought its elimination to the utmost practical extent should not be one for the oil refiner or producer, but rather for the transformer or switch maker. There were such wide possibilities for the taking up of moisture in handling, packing and transit that the variations in one consignment referred to by the authors were not surprising. Physical and chemical properties which fixed the general character of the oil could be so easily adhered to by the oil manufacturer on the one hand, and the elimination of the moisture, on the other hand, could be so easily ensured to a practically efficient extent by, say, filteration through beds of calcium chloride, that it seemed reasonable to think that the oil user was in a better position to take care of the electrical properties than the refiner. He did not suggest that the question of moisture had been overlooked by the authors, but he thought that it had hardly been given sufficient prominence where, in his opinoin and experience, it was deserving. He had already referred to the fact that alkalinity or acidity in mineral oils was of rare occurrence, and in view of this, it would be interesting to know whether the authors had any theory as to the changes which they observed in studying the effect of disruptive tests on the chemical and physical properties of oils, where they found changes not only in degree of alkalinity, after baking and testing, but also changes from slight acidity to marked alkalinity. One of the most interesting sections of the Paper was that dealing with the experiments on the relation between dielectric strength and temperature. The general trend of the curves obtained for solid insulating materials was rather in the opposite direction to those shown for the various oils. He was inclined to think that this striking difference between solid and liquid insulating materials was due to the much better dissipation of heat in the path of stress in oils. Reference to the viscosity figures for these oils gave support to this view, and parallel cases would be familiar to those experienced in the testing of insulating materials. For the reasons just stated, he could not agree with the authors in stating that makers of oil-cooled transformers were wrong or misguided in applying lower test pressures to transformers when they were heated up at the end of a test run, than after being allowed to cool. The dielectric which the transformer maker tested was not the oil, but various solid or laminated dielectric materials which had, to some extent at least, reverse electrical characteristics to those of oils at high temperatures. The relation of viscosity to temperature was a portion of the subject on which a great deal of work had already been done, although almost entirely in connection with lubrication. The relation between fall of viscosity with temperature and electrical properties should prove exceedingly interesting, because the general order of percentage decrease of viscosity with increase of temperature bore some relation to the surface tension of the oil, and the surface tension of the oil might be quite different in cases where oils of different origin gave identical results under physical tests at the usual testing temperatures. The authors would find some remarkable results in this direction when they made further investigations in connection with this part of their subject. Referring to the chemical side of the Paper, Mr. Beaver said, with regard to the detection of moisture, although the exsiccated cupric sulphate was very sensitive to the action of water, oil might be chemically dried, and improved electrically by such drying, beyond the point when this test ceased to be sensitive. Without doubt, the most delicate test was the stream of hydrogen bubbles given off from a small piece of sodium immersed in the oil, and as the nitro-prusside test for the detection of sulphur entailed the use of metallic sodium, there would appear to be little use for the dehydrated cupric sulphate. In regard to indicators, he found no necessity for testing the aqueous extract while hot, and personally did not prefer tincture of cochineal to the more usual phenol-phthalein and methyl-orange. He had always found phenol-phthalein reliable and did not understand the statement that it was not affected by the soaps of alkaline metals. He had some doubt as to the identity of the resinous bodies to which the authors frequently referred in connection with their samples, and wished to know whether they had been isolated as such or identified by such a test as the Liebermann-Storch test.

Mr. J. S. Peck (British Westinghouse Co.) remarked that from a practical point of view there were three necessary qualities in oil used for transformers: (*a*) High fire test, (*b*) high dielectric strength, (*c*) freedom from deposit under working conditions. The authors had dealt with (*a*) and (*b*), but had not touched upon the question of deposit at all. He hoped their investigations would extend to cover this question, for although there were oils on the market which were unsatisfactory as regards the fire tests and dielectric strength, it was very difficult to obtain an oil which would not throw down a deposit when worked at a comparatively high temperature. High dielectric strength was largely a matter of purity, while the method of obtaining a high flash point was well understood. Regarding the question of deposit, however, very little appeared to be known beyond the fact that some oils exhibited this defect to a marked degree, whilst others were practically free from it. This might

Digitized by Google

be said to be the most important question now confronting manufacturers and users of oil for insulating purposes. There was no advantage in purchasing expensive oil of great purity unless precautions were taken to maintain the purity of the oil during shipment. Oil would absorb a certain amount of moisture if exposed to a damp atmosphere, and when shipped in wooden barrels there was always a risk, especially when stored out of doors, that water would work in through the heads of the barrels. On this account the use of wooden barrels for shipping and storing had been largely done away with. The authors had devoted considerable space to the question of the specific resistance of oil, but in his opinion this was not of practical importance, unless this formed some identification of the dielectric strength of the oil. From the results this was apparently not the case. He agreed with Mr. Beaver, and therefore disagreed with the authors, in regard to the statement that a transformer should not be tested with a higher voltage when cold than when hot, because the oil had little to do with the insulation strength except in preventing surface discharges. Breakdowns usually occurred through the solid dielectric, and there was no doubt that this was weaker when hot than when cold. He thought it would be interesting to compare the effect of the alternating-current arc with that of the direct-current arc, as experience indicated that the carbonising effect was much greater with direct than with alternating current.

Mr. J. E. Southcombe (Henry Wells & Co.) said, speaking as a chemist with experience of oil investigation, he could not quite agree with some points raised by the authors as to the purity of the samples. In the first place, an examination of many samples of transformer and switch oils had not revealed the universal presence of alkali which the authors appeared to have observed. It was, in fact, an extremely rare thing nowadays to find alkali in oils of this type, and he could only say that if an oil submitted to him for adjudication contained any traces of this substance he would reject it at once as totally unworthy of any further consideration. The authors had apparently had somewhat abnormal samples under consideration. With regard to the question of moisture, the authors stated that they found oils containing as much as 0·57 per cent. of moisture, but it would appear that they had estimated this by drying at 100°C. and noting the loss. This would not give any measure of moisture content whatever, since the losses from volatilisation of the oil would always be an unknown quantity, and would totally vitiate the figures. There appeared to be a most unfortunate haziness with regard to the question of how much water there was in oils. He had conducted a long series of experiments on this matter from several points of view. Oil and water were immiscible, and if an oil contained water at all it was present in fine globules distributed throughout the mass. Now if the globules were big the water would quickly settle out of the oil, while if they were very fine indeed they might be retained for long periods, since the mixture would partake of the properties of an emulsion. Now if the globules were very minute there would have to be an immense number of them present to have anything like 0·57 per cent. of water in the oil; consequently, the water surfaces would be great, causing considerable thickening, and the oil would be very turbid. It was inconceivable that any self-respecting oil manufacturer would submit such an emulsion for transformers. Such cases did not need discussing, but what was a burning question was the influence of very minute traces of moisture on insulating properties. An oil might be quite bright and yet contain absorbed moisture, but such moisture was present only to the extent of about 0·1 per cent. or less. The quantitative estimation of such minute traces chemically was almost impossible, but he could say that the dielectric strength was a very delicate test. In his opinion variations in dielectric strength could be correlated very largely with these exceedingly minute traces of moisture, which had a far greater influence on the electrical properties than any so-called chemical impurity in well-refined oil of standard quality. There was very little evidence to show that disruptive discharge proceeded more readily in the presence of resins, &c. In fact, resin oils were admirable insulators. A study of the figures given in the authors' Paper showed that what they called resinoid content did not explain the variations in dielectric strength. He emphasised again the fact that in his opinion it was not chemical impurities but exceedingly minute traces of moisture that would explain many discrepancies in dielectric strength. The problem of how to get rid of this moisture resolved itself very much into a commercial question. Was it to be done by the oil manufacturer or by the transformer builder? There was no doubt that the oil man could supply a perfectly anhydrous fluid, but it could not be done if the electrician was going to ask for an oil at a price which his better sense must tell him would make it impossible to devote much attention to these minute but important details. Considerable success had attended drying the oil by electrical resistances immersed in the oil, but it would appear to him a better investment to pay the experienced oil manufacturer his price and demand from him an anhydrous oil. Although the question of chemical impurities did not appear so important as moisture in lowering the dielectric strength, yet it was absolutely imperative that an oil should be of the highest possible purity, since the influence of acids, and more particularly alkalis, on the windings was disastrous, while at the same time any tendency for the oil to resinify or oxidise on heating would materially affect its heat disseminating powers. It was unfortunate that the authors had not gone into this question more fully. In addition to the points they drew attention to, no specification would be complete which did not demand tests as to the durability of the oil on successive heating and cooling. On the electrical tests he could not speak with authority, but some experiments made by Mr. Lustgarten at the Manchester School of Technology, and the conclusions of Russell, did not confirm the authors' results at such short distances. Further the carbon produced by the passage of the arc required some considerable time to settle, and a sufficient interval must elapse before making a second puncture. The carbon produced was disseminated throughout the oil in a kind of semi-colloidal suspension of charged particles, which settled at varying rates in different oils. The speaker was at present investigating this phenomenon, and had obtained some most interesting results which appeared to be of supreme importance in the choice of a switch oil.

Mr. J. Lustgarten (Manchester School of Technology) said that of the properties mentioned in the Paper as requisite in a mineral oil one might add that evaporation must be small, and that no trace of sediment after repeated heating and cooling should occur. The authors mentioned that resinoid matters contaminated oil when stored in wooden barrels. He wished to ask the authors if the wooden barrels which were sent into this country from America were made of oak, because, if so, he hardly saw that resinoid matters would be likely to get into the oils with such construction of the barrels. As the authors recommended standardised methods of testing, and though they deprecated criticism of methods of taking the dielectric tests, it should be stated that the sparking voltage depended on many factors which the authors had not mentioned. These factors were: (*a*) The width of the glass vessel in relation to the spark distance and the size of the electrodes; (*b*) the position (depth) of the spark-gap in the oil; (*c*) the amplitude factor of the machine used; (*d*) the rate of growth of the testing pressure; (*e*) whether the electrodes were insulated or one was earthed; and (*f*) the shape of the electrodes. The amplitude factor was important, because if the machine had a peaky wave, the oil would break down very much earlier. Earthing one electrode altered the maximum potential gradient on the insulated electrode. With regard to (*d*), a modification of the method was to move the electrodes, keeping the testing pressure constant. As to the shape of electrodes, he could not see why the authors got the voltage distance curve for ¾ in. diameter spheres to lie below that of needle points, as it was shown that in the air the voltage distance curve lay above that of needle points. Speaking of his own results on oils, the larger-sized spheres gave curves lying above the smaller size, and obviously the needle point was a very small sphere, and for a given sparking distance and voltage the potential gradient was steeper with needle points. He had experimented with ½ in., ¾ in. and 1 in. spheres, and had obtained better results with large spheres than with the smaller ones, but the distances had to be greater than ⅛ in. With regard to the curves for spheres, these bent over as in the needle point curve. Dr. Russell some years ago suggested that the best way of expressing the dielectric strength of an insulating material was by the maximum potential gradient at breakdown. This for the parallel plate electrodes immersed in the dielectric would be V/X, and for spheres V/X*f*, where V = maximum voltage, X = spark-gap distance, and *f* a factor depending on X and the diameter of the sphere. The dielectric strength of the best oils was about 160 kv. per centimetre, and for medium oils about 100. The potential gradient for the oil in the curves on p. 13 of the Paper was rather low, 80 kv. per centimetre. The authors remarked that the dielectric strength improved with flashing over, and was due to traces of moisture and impurities being burnt out. This was particularly apparent in an oil submitted to the speaker to test. The breakdown voltage went up from 42 kv. to 80 kv. (R.M.S.) in 20 days with a test taken once every 24 hours, but after repeated breakdowns the strength diminished, 80 kv., 71·2 kv. and 63·6 kv. being readings taken on three consecutive days. In testing oil sufficient time should be given to allow air bubbles to rise and finely-divided floating or colloidal matter to settle, as they would seriously affect the results, especially at the small sparking distances. In a particular case the breakdown voltage a few minutes after pouring in was 10 kv., half an hour afterwards 17 kv. and 24 hours later 48 kv. (in the latter test traces of moisture must also have been removed). The authors found that the dielectric strength of the oils increased with temperature. This result seemed the reverse of what might be expected. In solids it was the reverse. Did the authors find this to hold after repeated heating and cooling of one specimen in order to eliminate traces of moisture and impurities before conducting the test? For drying oils he found that hot air and sodium answered very well. In one case a transformer oil treated with sodium increased in strength from 107 kv. to 122 kv. per centimetre.

Mr. D. B. Mellis, in reply, said in connection with Mr. Beaver's remarks, the purpose of putting down along with the observed physical behaviour of the oils examined the result of their chemical examination also was not to infer that the physical properties found were due to chemical impurities. Although had no chemical examination of the oils been made it would always have been open for anyone to say that variations in the behaviour of the oils under discussion were due to variations in their degree of purity. With regard to the slight variations in the reaction of oils observed after testing for dielectric strength, these might be due to several causes. For instance, electrolytic action might change some of the impurities contained in the oil from acid to alkali and *vice versa*. Or again, owing to the high voltages used, the air surrounding the testing vessel and in contact with the oil became ozonised, and nitrous oxide was also formed. These substances might easily affect the reaction of so nearly neutral a liquid as the oil usually was. Mr. Beaver seemed to think that it was asking too much of the oil people to expect them to supply oil to a standard of specific resistance. The authors did not agree with him in this matter, as the specific resistance test was really a very delicate test for the chemical purity of the oil in question. In fact, the importance of the specific resistance test was that no oil having a relatively large amount of water or other harmful impurity would have a high resistance. If copper refiners could work to a specification of specific resistance it was not unreasonable to ask oil suppliers to work to a similar one. Mr. Beaver remarked that the authors did not attach sufficient importance to the presence or absence of water. This was unintentional. They did not labour the point as they thought it fairly self-

Digitized by Google

evident. They considered it of the utmost importance for the refiner to supply absolutely dry oil, but it was of no use his doing so unless the necessary care were taken to keep it dry. When the user had to dry his own oil they would suggest warming it up in a vacuum oven to a moderate temperature. Too high a temperature must not be employed or the nature of the oil might be changed. If possible, when in the vacuum oven, dry air should be allowed to bubble through the oil, so as to stir it up and help the evaporation, and by "dry air" they did not simply mean "hot air," but air which had been freed from moisture by passing it over calcium chloride or, better still, phosphorus pentoxide. The method suggested by Mr. Southcombe of stirring the oil with a cage containing metallic sodium would appear to have the disadvantage that caustic soda would tend to replace the water, and would afterwards attract to itself much more water, unless the vessel were hermatically sealed after treatment of the oil. Mr. Beaver remarked that the other physical properties such as viscosity and flash point did not appear to have any relation to the electrical properties of an oil; in this connection the authors would like to remark that a sample of ordinary illuminating paraffin oil bought at a very cheap rate gave a curve of dielectric strength at least twice as good as the best transformer oil, and needless to say both its viscosity and flash point were very low, far lower than those of any transformer oil. It was also interesting to note that the dielectric strength of any transformer oil increased with rise in temperature, while its viscosity fell. This relation between viscosity and dielectric strength might be accidental, both being due to some molecular condition. Mr. Pollard quite agreed with Mr. Beaver that variations in electrical properties might be caused to a very great extent by very small proportions of moisture, but the question of alkalinity was of importance because a very slight trace of alkali caused absorption of moisture. He was not in favour of filtration through calcium chloride for drying oils, but preferred Mr. Peck's vacuum oven process. Another good method of eliminating moisture was by blowing hot dry air through the oil. Whilst endorsing Mr. Beaver's remarks as to the sodium test, he found that the exsiccated cupric sulphate test was sufficiently sensitive when suitably applied. With regard to indicators, he had no intention of advising the testing of the aqueous extract whilst hot, but cochineal had the advantage that it could be used for hot liquids, whilst methyl orange could not, and, moreover, the colour change of methyl orange, with traces of alkali, was not easily observed, unless the indicator were first made feebly acid and then carefully neutralised. It seemed to be generally taken for granted that the alkali in oil invariably existed as hydroxide. This was very far from being the case, and consequently, when phenol-phthalein was used as an indicator, considerable traces of alkali escaped detection. The neutrality of phenol-phthalein to soaps permitted its use in soap analyses for the estimation of free caustic alkali, whilst the subsequent volume of acid required to give neutrality with methyl orange was a measure of the alkali combined with fatty acids, &c., or existing as carbonates, borates, &c. However, soaps of the alkali metals were very seldom found in mineral oils of the type under consideration, although aluminium soap was by no means infrequently met with. The exact nature of the "resinoid" matter was not determined. In most cases it appeared to be tolerably pure resin, but in several instances examination revealed admixture of other substances, hence the employment of the term "resinoid matter" instead of "resin." With regard to Mr. Southcombe's statement that it was an extremely rare thing nowadays to find alkali in oil of this type, out of considerably more than 100 samples examined during the last 18 months or so, at least 80 per cent. had been found to contain alkali, sometimes in slight, sometimes in very distinct traces, but had phenol-phthalein been used as an indicator, no doubt practically the whole of these would have been returned as neutral. Comparative tests had demonstrated that cochineal and methyl orange were more than ten times as sensitive to alkaline carbonate than was phenol-phthalein. All the samples were obtained from well-known makers of transformer oil. They could not, therefore, be considered to be abnormal samples, as Mr. Southcombe suggested. Of all the oils discussed in this Paper only one of them showed an acid reaction—viz., H_5—all the others being neutral or alkaline. With reference to Mr. Southcombe's criticism of the authors' method of making tests for dielectric strength, in which he quoted Russell as saying that such determinations were not reliable when tests were made over short distances, and that consequently high voltages must be employed, the authors would point out that when Russell made this statement he was discussing the experiments of Hobbs, who tested over microscopic distances down to 3×10^{-7} cm., and he went on to say that it was not safe to calculate dielectric strengths from the observed disruptive voltages when the electrodes were less than 1 mm. apart, and suggested that for accurate work at least 0·5 cm. should be tested over. Now, as the authors' distances range from about 0·5 mm. to over 1 cm., they did not suppose that Russell would take exception to the lowness of the voltages used. Their results were in accordance with Russell's statement, in that the more consistent readings were generally obtained with the higher voltages than with the lower ones. Mr. Southcombe's tests were apparently mostly made using balls as the electrodes, and in his case air bubbles would be more likely to give trouble than in the authors' case. In connection with Mr. Peck's remarks on deposit, one usual explanation offered was that varnish, supposed to be oil-resisting and used in transformer insulation, was not actually so, and that it dissolved out, or partially dissolved out, forming a more or less gelatinous solution, which, by electrostatic attraction, clung to the windings and impeded the free circulation of the oil. This, however, did not appear to cover every case observed, and they were forced to suppose that the thickening, in some cases at least, was due to polymerisation of some of the hydro-carbon of which the oil consisted, or even to chemical change brought about by repeated heatings and cooling. This was a question for chemists rather than electrical engineers to investigate. The authors fully agreed with Mr. Peck in his remarks about carelessness in handling oils sent out in casks, and considered that, for electrical work, nothing but hermetically sealed metallic drums should be permitted. While agreeing with Mr. Peck that high dielectric strength was a most important feature, they did not agree that a high resistance was not of much use, as the latter was only obtained with very pure oils and might be taken as a measure of their chemical purity. With regard to the authors' suggestion as to testing transformers with a higher voltage when hot than when cold, Mr. Peck disagreed on the ground that oil was not the principal insulating medium. This criticism, of course, would not hold good in the case of a transformer so designed that the oil was the principal insulator. Referring to the much greater relative amount of carbonisation which took place in the oil tanks of direct-current controllers or switches than with alternating current, the fact of the alternating current passing through zero twice a cycle gave the oil a very much better opportunity of extinguishing the arc in the latter than in the former case, and also no highly inductive arcs had to be quenched, which was not the case with direct currents. Replying to Mr. Lustgarten, when American oil was shipped in barrels these were usually made of oak, but in the case of Russian oil steel drums were generally used. The glass containing vessel of the apparatus illustrated was about 2 in. diameter, and as the electrodes were placed axially it was obvious that the distortion of the electrostatic field, due to the high specific inductive capacity of the neighbouring glass, would have no effect on the field between the two electrodes, which were never separated by more than 0·4 in. The curve of voltage of the alternator used did not differ very much from a true sine curve. The value in kilovolts given on the curves of dielectric strength was expressed in virtual volts. Besides the maximum voltage the length of time during which the voltage was applied decided the limiting sparking distance. From this they would conclude that higher dielectric strength would be obtained with a higher frequency. Neither of the electrodes was earthed, but as everything was very well insulated and the voltages used were never higher than about 25,000, earthing should not have made much difference. In reply to Mr. Lustgarten, it was not safe to argue as to the phenomena of breakdown in liquids from experimental results obtained in air. J. J. Thomson showed that when ions were present the electrostatic field was distorted, and could not be calculated from the geometry of the electrodes only. It was obvious, therefore, that if in the one case the ions could freely move about and in the other they were relatively stationary the distribution of the electrostatic field would be different in the two cases. Another suggestion they would offer was that, when testing with one or both the electrodes pointed, only a very small volume of the oil was subjected to intense dielectric stress, whereas when testing between balls a very much greater volume of oil would be stressed. Owing to the fact that the oil was probably far from homogeneous there would be a much greater likelihood of a weak part being stressed and broken down in the latter than in the former case. In a similar way it would not be safe to estimate the dielectric strength of a mile of cable as equal to the value experimentally found for a yard length. The only apparent advantage in testing between balls was that the absolute value of the physical constant "dielectric strength" could be more readily calculated than when points or a point and disc were used. As the authors found the latter gave the more regular results, it was the more suitable for determining the relative dielectric strengths of oils under similar conditions. Further, the authors did not state that the curve connecting sparking voltage and distance between spherical electrodes was linear. Of the oils designated by the letters H_1 to H_7 all were ordinary commercial samples, none being appreciably better nor worse in their purity than those supplied in bulk to large purchasers. At the commencement of the Paper the authors referred to the splendid curve of high dielectric strength widely circulated but rarely attained in practice, they therefore urged that in dealing with commercial oils in everyday use the present researches had tended towards practical utility.

CORRESPONDENCE.

ON THE EFFECT OF SHUNTING INDUCTIVE COILS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In his interesting article on the effect of shunting a choking coil with a non-inductive resistance, Mr. Howe points out that the *impedence* is not increased by the addition of such a shunt. If, however, he had drawn his vector diagrams to illustrate the effect of shunting a highly inductive coil when the latter has *in series with it* a non-inductive resistance, he would have found that the total impedence of such a circuit may be increased by connecting a non-inductive shunt across the choking coil. This effect was explained by the writer in his book on Alternating Currents (published in 1898), and it is not unlikely that both Mr. H. E. Harrison and Mr. A. Campbell may have had such a circuit in mind when referring to the increased impedence.

Given a non-inductive resistance connected in series with a choking coil across an alternating supply of constant voltage, it is an undeniable fact that the current flowing in such a circuit can actually be *reduced* by connecting a non-inductive shunt across the choking coil.—Yours, &c.,

Springfield-lane, Salford, April 28. ALFRED STILL.

THE WESTMINSTER STREET LIGHTING CONTRACTS.

The following letter has been sent by the St. James' & Pall Mall Electric Light Co. to the Town Clerk of the Westminster City Council, and copies have also been forwarded to all members of the Council:—

DEAR SIR: I am in receipt of your letter of the 15th inst., informing me that the City Council have not seen their way to accept the tender of this Company, dated the 14th March last, for public lighting in District D of the City, and reminding me that the existing contracts of the Company with the Council for this purpose will expire on the 10th November next.

With regard to this matter and more especially to this notice that the existing contracts will be terminated at that date, I would respectfully point out that this Company has been placed at a great disadvantage by the form of the recent specification and tender to which strict adherence is enjoined. For instance, Clause 2 of the General Conditions of Contract stipulates that the contractor may tender for the lighting of all or any of the districts A, B, C and D mentioned in the form of tender, treating each district as a separate unit, and that the Council *inter alia* may accept any such tender in respect of any part of any district to the exclusion of the remainder of the same district, and for this purpose may sub-divide any district, but the contractor is not permitted to tender for the lighting of any part of a district or even to submit a different price for that part which the special circumstances of the case may justify.

Under the existing contracts this Company maintains at the uniform charge of £17 per lamp per annum a total of 66 arc lamps consisting of 16 660-watt flame arc lamps in Regent-street which give an illumination according to the tests of the City Engineer of 3,575 c.p.; four 440-watt flame arc lamps in St. James's-street which give an illumination of 1,800 c.p.; and 46 660-watt white arc lamps in Piccadilly, St. James's-street, Pall Mall, &c., which give an illumination of 900 c.p. In addition to these there are five white arc lamps in Piccadilly-circus which are maintained at the rate of £2. 10s. per lamp per annum, and a charge of 2½d. per unit for electricity consumed by meter, but this small circuit need not be included as part of the above.

For the above total of 66 lamps a special circuit of mains has been laid down in connection with a complete generating and accumulator plant, the system being controlled direct from the works of the Company. To extend this system for the whole of District D, for which the Company had to tender, involved a capital outlay for additional mains and plant, which rendered the cost on a five year contract practically prohibitive. Competition with the tender of the Gas Company had therefore under the circumstances to be directed to the longer period of a 15 year contract, and on this basis the charges of this Company for the 3,000 and 1,800 c.p. lamps are entered at £22 and £17. 10s., as compared with those of the Gas Company at £20. 5s. and £14. 5s.

But with regard to the above circuit of 66 arc lamps the circumstances are different. This Company would have to incur no additional capital expenditure, except that of providing the new flame arc lamps in place of the existing white arc lamps, and had the form of tender permitted, these matters would have been fully taken into account and a special price submitted. This, on the basis of the estimates prepared for the original tender, would be:—

For a five year contract with the option to the Council to renew for the 10 or 15 year period the maintenance of the existing 16 flame arc lamps in Regent-street to the 3,000 c.p. standard and the installation and maintenance of the other 50 lamps in Piccadilly, St. James's-street, Pall Mall, &c., with new flame arc lamps to the 1,800 c.p. standard for the inclusive price of £1,122 per annum, representing an average charge of £17 per lamp per annum for both sizes. No charge would be made for any installation costs in connection with the above, and the Company would undertake to have the whole of the alterations completed and in full working order by November next.

The efficiency of the flame arc lamps in Regent-street is an established fact, and as the carbons are renewed each day and the current of electricity maintained at a constant quantity there can be no deterioration of the illumination. On the other hand, no gas lamp of equivalent illuminating power and effect has yet been exhibited, and on account of the deterioration of the gas mantles employed the resultant light must be subject to considerable degeneration when in regular use.

By the arrangement proposed by this Company a total of 138,000 c.p. is provided at an inclusive cost of £1,122 per annum as compared with the cost of £1,127 per annum for the equivalent candle-power derived from gas lighting, to which must be added the further cost of installation of £140 per annum, for which no charge is proposed by this Company. Further, the maintenance of the electric light circuit involves no further opening of the roadway of these important thoroughfares, whereas the installation of a high-pressure gas service in this case will surely necessitate the opening of the whole length of these streets.

In view of all the circumstances which are set out in this letter, my Directors ask that it may be read at the next meeting of your Council, in the hope that a modification of their recent resolutions may be made which will provide for the continued supply by this Company of 66 arc lamps of the improved type at the same inclusive cost as heretofore.

They take the liberty of urging this course upon your Council from the point of view of the public benefit, having regard to such matters as the satisfactory illumination which has been demonstrated in Regent-street, the actual cost of this method of lighting, and the important fact that no disturbance whatever of the roadways of these important thoroughfares is involved therewith, and in this connection they desire to call attention to the reiterated assurance given by Mr. Abady to your Mayor that your Council have the right to omit the lighting of Regent-street and Piccadilly from the contract should they think fit to do so.

I shall be glad to hold myself at your disposition for any information that you may require, or to consider carefully any modification of the above arrangement that the Council may suggest.—I am, dear Sir, yours faithfully,

(Signed) F. J. WALKER,
General Manager and Secretary.

STREET LIGHTING IN WESTMINSTER.

Westminster City Council yesterday discussed a section of the Works Committee's report in regard to the distribution and cost of the lighting, under the Gas Light & Coke Co.'s recent tender, which had been accepted at the previous meeting for the street lighting of several districts, including Regent-street and Piccadilly, at present lighted by the St. James' & Pall Mall Electric Light Co.

Councillor PULLMAN said he had been so pertinaciously approached by ratepayers of his ward that he raised once more the question of the removal of the arc lamps. It had been pointed out to him that the electric lighting of Pall Mall, part of Piccadilly, Piccadilly Circus, Regent-street and St. James'-street would cost only £250 more than gas lighting. Although he, personally, was satisfied that the new light would be equally satisfactory, he moved, in order that the matter should be ventilated, that they disagree with the Works Committee's report so far as the streets he had named were concerned.

Councillor GATTI said there would be a distinct advantage in continuing the lighting by arc lamps, which at present existed in Regent-street. The arc lamps were there, and they would save the trouble and interference with traffic, and there would be also an actual reduction in the cost of the lighting. They had a perfect right to reconsider the matter.

Councillor ABADY (Chairman of the Works Committee) said the standing orders barred the Electric Light Co. from having their tender reconsidered on the ground that contractors were prohibited from canvassing members or officials of the Council, and the letter that had been sent by the company amounted to canvassing. Their specifications were clear, and if the Council allowed that Dutch auction sort of business they should also give the Gas Co. another chance of having a shot at the electric light prices. The St. James' Co.'s letter which had been sent to the Town Clerk stated that the contractors were not allowed to submit a different price for a district in which special circumstances applied, but the conditions of contract stated that the contractor could make different charges for different districts.

Mr. PULLMAN said he would withdraw his motion as he was satisfied with Mr. Abady's explanation.

Capt. JESSEL congratulated the Chairman of the Works Committee, but he did not think there was anything improper in the letter of the St. James' Co. It was customary when a company had a case to defend or to put forward. He remembered that the same thing was done by the Gas Light & Coke Co. many years ago.

Councillor GATTI said the tables which had been put before the Council at the last meeting referred to an average for 10 years, but he could not see how any average could be taken. There had been a tendency to make things difficult for the Electric Light Co. Conditions were imposed which he did not think could be of any benefit to the Council, but which might have been a great burden to the contractor. He quoted as an instance a condition that if a lamp were out for five minutes you got the light free for about two months. Mr. Abady had, all through, for the purpose of comparison, taken the five year period, and when a contractor had to spend a certain sum of money, and only had five years to recoup himself, that made it necessary to make a correspondingly high charge for the light. On the 15 year period the prices would have been much nearer.

Councillor BINGHAM did not agree with Mr. Abady that the Electric Light Co. were not prevented from tendering for certain portions at different prices. Looking at it from a lawyer's point of view it might not mean that, but the Company had not come for an explanation, and he thought they must suffer for it. He was afraid the removal of the electric light would do away with competition. He went on to say that the 3,000 nominal candle-power electric lamps at present in use gave 3,500 c.p., whereas the only 3,000 nominal candle-power gas lamp of which he knew (that outside the Mansion House) only gave 2,500 c.p. The Regent-street arc lamps gave a magnificent light.

Councillor ABADY said the reason they took the five years' period in making a comparison was that the Committee would not consider a contract for more than five years at the outset, but wished to reserve the right to enter into an additional five years' contract at the end of the first five years, at the 10 years' prices.

The Committee's report was ultimately adopted, without exception.

OERLIKON VARIABLE-SPEED THREE-PHASE MOTORS.

The use of centrifugal and turbine pumps, and particularly of ram pumps, has hitherto been considerably limited in places where a three-phase current supply is available, as speed regulation with three-phase motors entails reduced efficiencies when resistances are used in the rotor circuits.

The Oerlikon variable-speed three-phase motor of the induction type, which has been used for many years past and which is particularly well known on the Continent, has provided a solution of this difficulty. Until recently it has only been possible to build such motors of the two and four-speed step type, but of late, say, for the last two years, the Oerlikon works have succeeded in making machines with five and six-speed steps, thereby widening the range of utility of this class of machine very considerably, and making it particularly adaptable to mining work for the driving of haulage gears, main fans, pumps, &c.

In the case of a 100 B.H.P. Oerlikon variable-speed induction motor driving a three-stroke ram pump in a well-known Scottish mine, the motor is built to run at 105, 360, 485, 725 and 970 revs. per min., and gives at these speeds 10, 34, 48, 70 and 100 B.H.P. respectively on the spindle shaft. It could, of course, have been designed to give any other range of output and also, for instance, a constant output of 100 B.H.P. at all speeds should this have been necessary. This motor is supplied with three-phase current at 2,200 volts between phases and a frequency of 50 cycles. The rotor diameter is 35·25 in., and the width of the active iron of both rotor and stator is 10 in., the air-gap being approximately $\frac{1}{16}$ in. The

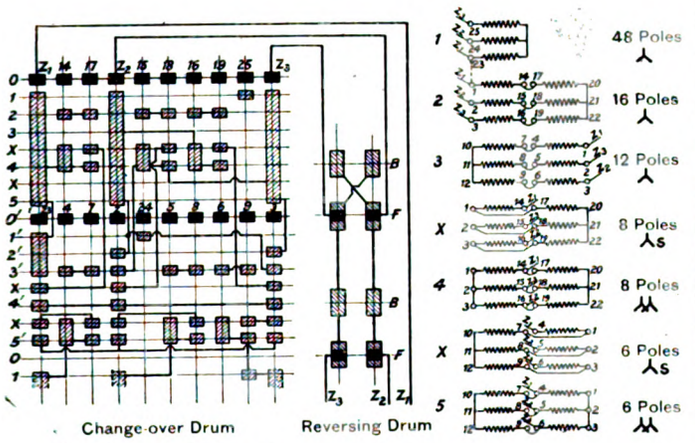

FIG. 1.—DIAGRAM OF CONNECTIONS OF OERLIKON CONTROLLER.

stator has 144 half-open slots measuring in section 0·45 × 2·55 in. The rotor has 213 half-open slots measuring 0·195 × 1·02 in. The stator is equipped with three independent sets of drum windings, equally divided in the slots. The first winding for the lowest speed has 48 poles. The two other windings are arranged for two sets of poles in the ratio 1:2, viz., 16 and 8 poles and 12 and 6 poles respectively. The first winding has per slot 55 turns, 0·043 in. diameter; the second winding has 24 turns of 0·075 in. diameter, and the third winding has 18 turns of 0·0857 in. diameter. The windings for the 16 and 8 poles are formed of eight sets of coils, and the windings of 12 and 6 poles are formed of six sets of coils, which are connected in series for the higher number of poles and in parallel for the lower number of poles, as indicated in Fig. 1.

The design of the rotor is the simplest feasible. It is provided with a squirrel cage winding of copper bars without insulation, and short-circuited at both ends by means of cast-on brass rings. The pole change-over switch is also of extremely simple design. The contact pieces are so arranged on the controller drum that no crossings of the leads beneath the individual contact pieces takes place, so that the insulation of the individual contacts against the drum and between each other is perfect. There are 20 contact fingers in number, 17 of which are required for the pole-changing device, and three for the leading-in wires (*see* Fig. 1). The contact drum is provided with a ratchet giving seven distinct positions, five of which correspond to the five different speed steps, whilst the intermediate positions are so-called "transition positions," from 12 to 8 and from 8 to 6

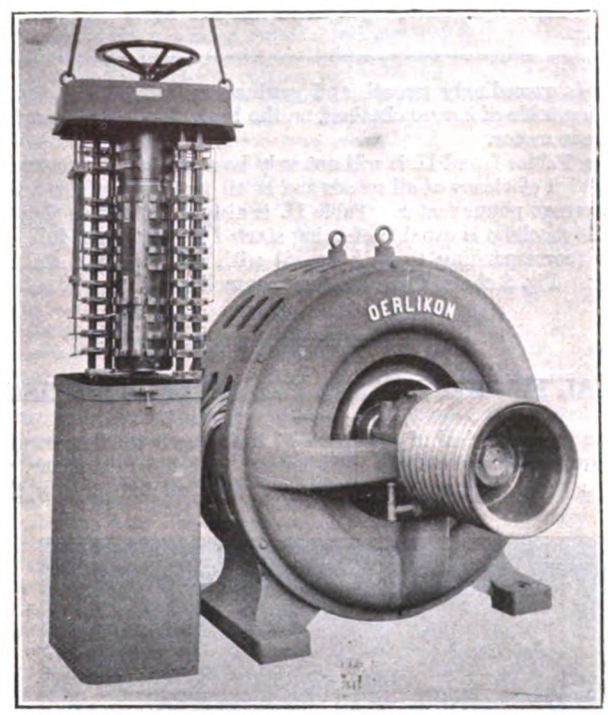

FIG. 2.—OERLIKON VARIABLE-SPEED 3-PHASE INDUCTION MOTOR.

poles. The pole change-over switch is equipped with a reversing drum, which moves freely on the shaft of the main drum, but so interlocked that it can only be operated when the main drum is in the zero position, *i.e.*, when the stator is disconnected. The whole pole change-over and reversing gear is oil-immersed. Such pole change-over drums with motors have been in operation for four and five years without having necessitated the replacing of contacts, thus showing that the life of the whole combination is very good. The starting up of the motor by means of this pole change-over

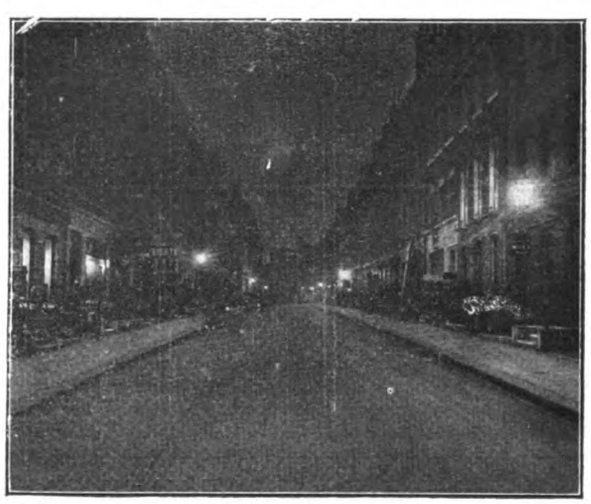
* Starting torque tested by Prony's brake. Lever 1·58 m. long; 45-50 kg.

device is exceedingly smooth and gradual, as will be seen by the adjoining table of figures obtained on the brake tests carried out with the above motor.

From Tables I. and II. it will not only be seen that the motor has a very high efficiency at all speeds and at all ouptuts, but also a very high average power factor. Table II. is also of interest as showing that the machine is capable of being started up at normal full load torque (corresponding to each speed) with a very small starting current. Fig. 2 shows the motor and controller.

METAL FILAMENT LAMPS FOR STREET LIGHTING.

There is a good deal of discussion at the present time concerning this development of electric illumination, and the future has, we think, a great deal of interest for the electrical industry in this



(Reproduced from an untouched photograph.)

A Typical Example of Osram Side-Street Lighting in the West End of London.

direction. For this reason any example of actual street lighting by this means is pertinent to the question at issue, and we give herewith a photograph which shows the illumination of a street in the West-end of London carried out by means of a combination of two 100 c.p. Osram lamps fitted in lanterns with special reflectors. It needs no expert to decide that the example is a particularly effective one.

"The Inventions of Nikola Tesla."—"The Electrician" Co. have inquiries for copies of Mr. T. C. Martin's book, published about 1894, entitled "The Inventions of Nikola Tesla." Anyone desirous of disposing of copies of this book will please address the Publisher, 1, 2 and 3, Salisbury-court, Fleet-street, London.

RADIOTELEGRAMS.

Returns have just been presented to Parliament showing:—

1. The total number of Unofficial or Non-Departmental Radiotelegrams to and from commercial ships at sea.
2. The number dealt with at each Wireless Station.
3. The number of such Radiotelegrams calling for assistance to ships disabled and for those in danger, with the names of the ships and the results of any such appeals.
4. The total number of licences held by shipowners, the number and names of ships so covered and actually fitted, and the trades in which the ships are engaged.
5. The total revenue derived by the Post Office from such Radiotelegrams.
6. The total number of Stations licensed in the United Kingdom apart from ship installations, specifically stating the number in the county of London.

Following are the particulars given:—

1. Total number of unofficial or non-departmental radiotelegrams exchanged between the shores of the United Kingdom and commercial ships at sea from March 31 to Dec. 31, 1909, 34,496.
2. These radiotelegrams have been dealt with at Bolt Head 262, Caister-on-Sea 680, Crookhaven 18,599, Heysham Harbour 123, Lizard 4,434, Malin Head 3,423, Niton 1,779, North Foreland 477, Parkeston Quay 592, Rosslare 875, Seaforth (Liverpool) 3,252.
3. No radiotelegrams embodying a general call for assistance to ships disabled or in danger were received at any of the above stations during the period in question, but in three cases vessels which were in distress communicated with their owners or agents through one or other of the stations. Names of vessels and precise results of the communications not known. In 16 cases vessels in distress were reported by certain lightships which communicate with these stations by means of wireless telegraphy.
4. Total number of licences held by shipowners on Dec. 31, 1909, in respect of ships registered in the United Kingdom, 32; number of ships covered by these licences, 116.

The names and trades of these 116 ships are given in the Return, and include five submarine cable steamers (the "Buccaneer," "Cambria," "Colonia," "Mackay-Bennett" and "Minia"), six vessels engaged in the West Indian fruit trade, 95 passenger steamers, four cargo and passenger steamers, one general cargo steamer, and four oil steamers.

5. The revenue (partly estimated) derived by the Post Office from radiotelegrams mentioned in (1) and (2) represented (*a*) coast station charges £1,120; (*b*) inland telegraph charges £1,115, total £2,235. It is noted that the Marconi stations only came into possession of the Post Office on Sept. 29 last, and the Lloyd stations on Nov. 1.
6. The total number of licensed stations in the United Kingdom on Dec. 31 (apart from ship installations) was 260, of which 241 were licensed for experimental purposes only. The total number of licensed stations in the County of London at the same date (all for experimental purposes) was 58.

ATLANTIC CABLE RATES.

The Postmaster-General's Bill providing for the control of cable rates by the Railway Commission was passed by the Railway Committee of the Canadian Senate on Tuesday.

The Bill was amended by eliminating the clause: "Any provision of any special Act inconsistent with this Act is repealed." The amendment permits the Commercial Cable Co. to retain the privileges it possesses in Canada by special legislation. The Act will only be valid so far as it is concurrent with legislation in the Imperial Parliament.

Mr. Lemieux, the Postmaster-General, expressed the opinion that the proposal to have three scales of charges for urgent (1s. a word), deferred (6d.), and Press messages (3d.) would work satisfactorily.

Mr. Dickenson, vice-president of the Commercial Cable Co., combated this idea, and said: Owing to their world-wide extent there were no idle hours on the cable lines and no deferred messages. The plan had been tried and abandoned. The companies might escape control by landing their cables at Newfoundland.

Mr. Lemieux said that Mr. Sydney Buxton, the former British Postmaster-General, promised to introduce concurrent legislation in the British Parliament.

Amendments to the Bill have been adopted which make its operation dependent on the passage of an Imperial Act.

Mr. Geo. Gray Ward, vice-president and general manager of the Commercial Cable Co., has addressed the following letter to the Speaker of the Canadian Senate:—

I understand that the bill which has recently passed the House of Commons of the Dominion of Canada, for the purpose, among others, of regulating or controlling the rates of cable companies owning trans-Atlantic cables, has been or will soon come before the Senate, and, accordingly, I take the liberty of addressing you on the subject, for the purpose of pointing out that the proposed reductions cannot be justified by business conditions or the status of the cable companies themselves. None of the Atlantic cable companies are earning more than a fair return. Some are not even earning that, because of the loss of income from disabled cables and the enormously increased charges for maintenance. To reduce rates would be to reduce income still further.

There is no reason to expect that the trans-Atlantic cables will be free from damage or breakage in the future, any more than they have been in the past. On the contrary, the

Digitized by Google

agencies which inflict the injury are multiplying and extending the field of their operations, and the cable companies must take into account the probabilities that their repair bills and loss of traffic will increase and will not diminish. One of our cables was damaged last year about 65 miles from our cable landing at Dover Bay, Nova Scotia, and we were in consequence deprived of its use for three months. When making the repair our repairing ship found that for a distance of 2¼ miles the cable had been caught about every 10 fathoms by steam trawlers, and had been flattened, twisted and subjected to great strain. A large number of steam trawlers are now fitting out in readiness for this season's fishing, and we dread the damage which they may do us, and which we see no way to avert. The strongest, newest and best cables are not immune from the depredations and devastations of these trawlers.

The Commercial Cable Co. has had three cable ships at sea at one time repairing or replacing disrupted cables. For over six months continuously during the past year we at no time had our entire facilities working, there being some break somewhere during all that period. The expense connected with all this has been enormous, to say nothing of the loss of business on account of not having complete facilities. In fact, the menace to the business is so great that we have decided to lay still another cable in the Atlantic Ocean, although such additional cable is entirely unnecessary to our present business if we could be sure of having our present facilities uninterrupted. Then there is our competitor, the Western Union Telegraph Co. We are told that for nearly nine months both of its cables have been entirely disrupted and out of use. The Direct United States Cable Co., which has one cable in the Atlantic Ocean, has also been in trouble during the past winter. All the cable companies without exception have had these troubles, and the aggregate expenditure for interruption and repairs has been enormous.

This demand on the part of Canada for reduced rates is not justified. Canada already enjoys a much lower rate than would be possible if the rate were to be fixed for a cable service dependent on Canadian traffic alone. It is the large volume of United States traffic that renders possible the low trans-Atlantic rate for the smaller volume of Canadian traffic. The cable rates across the Atlantic are the lowest cable rates in the world. The companies, and especially this company, have shown their friendly disposition towards Canada already by making a special rate as a matter of special gratification to Canada for the traffic in which Canada herself is specially interested—namely, the traffic between Australia, Canada and Great Britain.

Mr. Ward encloses a reprint of a letter which he sent in January, 1909, to the Committee on Foreign and Insular Trade, of the New York Board of Trade and Transportation. From this letter we extract the following:—

The disposition of the cable companies to meet public requirements is conspicuously shown in their attitude towards code language. The cable companies have gradually relaxed their rules and have admitted artificial or manufactured words, which are supposed to have some resemblance to real words. These so-called words really represent 10 figures each; the 10 figures are two groups of 5 figures, and each group of 5 figures represents a separate code word, and each code word easily represents, on the average, at least 10 plain words. The net result is that each of the above so-called code words, representing at least 20 words in plain language, is transmitted at a total cost of 25c. It is almost impossible to transmit by cable these words rapidly and correctly. The result is that the carrying capacity of a cable is reduced over 25 per cent. In addition to that, many of the so-called words have to be repeated. This places upon the cables a large amount of unremunerated work, as repetitions are not charged for. It also delays a great deal of paid work. By reason of all this the earning power of a cable is very greatly reduced, while the expense for operating is increased. When it is borne in mind that 98 per cent. of the cable messages are in cipher code, and each code word, as explained above, represents at least 20 plain words, it will be seen that cablegrams in code bring the rate down to less than 2c. a word for the translated message.

The 25c. rate is a fair rate. It is no more than is necessary to pay operating expenses and to keep the plant in thorough repair and readiness to furnish the best possible service in point of regularity, accuracy and speed, and to pay a very reasonable return on the money invested. The service rendered is worth the money, and cannot be rendered for less. The only comparison to be made with it is the State-owned British Pacific cable, which in its best year compelled the taxpayers to increase their taxes to the amount of £62,362 per annum.

LEGAL INTELLIGENCE.

Corporation of London v. County of London Electric Supply Co. (Ltd.)

On Friday last Mr. Justice Parker heard a motion for an interlocutory injunction to restrain defendant company from breaking up or laying their electric mains across London Bridge without first obtaining the consent of plaintiffs (the trustees of the Bridge House Estates), and also to restrain the company from proceeding with a certain arbitration with reference to the same matter.

Mr. A. J. Walter, K.C., and Mr. C. L. Chubb were for plaintiffs; and Mr. Balfour Browne, K.C., and Mr. Tyldesley Jones for defendants.

Mr. A. J. WALTER, K.C., in opening, said that defendant company had certain areas of supply both on the north and south sides of the Thames, and the object of the London Electric Supply Act of 1908 was to enable the defendants and certain other companies scheduled to the Act to connect the various areas of supply. The preamble stated the object of Act to be to enable the companies to connect their undertakings with the undertaking of any other person or company supplying electricity in the County of London, making connections between any two or more areas which the authorised undertakers were authorised to supply or any such areas with the generating stations. It enabled the undertakers to have a generating station outside the area of supply and the County of London Electric Supply Co. in particular to connect its two areas, north and south of the Thames. In laying the electric mains for that purpose the undertakers were given powers to break up streets within their area of supply. London Bridge was not within any area which the County of London Co. was authorised to supply. They had no powers, therefore, under that section to do what they were proposing to do. For breaking up streets not within any area they were authorised to supply by a later section of the Act it was provided that they should have power, but subject to the provisions of the Electric Lighting Act of 1882. They were entitled to any powers they could get out of the Act of 1882. They had power to lay down electric mains in such positions and of such dimensions as might be agreed between the authorised undertakers and the local authority of the district, and failing agreement, to be settled by an arbitrator to be appointed by the Board of Trade. Under the Act of 1908 for powers with regard to streets not within any area of supply they were referred back to certain sections of the Electric Light Clauses Act of 1899 and the Act of 1882. The Act of 1899 was a short one and, except so far as any provisional order was concerned, it did not apply to the City of London. London Bridge was not repairable by any local authority. It was repairable by the Trustees of the Bridge House Trust, who were the plaintiffs in this action. No part of such repairs were charged in the rates. Defendants could, therefore, break up London Bridge if they were specially authorised to do so by their special order, but the company had no such powers. London Bridge was, in fact, unique in that it was not within any area of supply. London Bridge was private property dedicated to public use. There was no provision anywhere which authorised any work to be carried out by the undertakers under the Act of 1908, and therefore it was necessary for the Court to go back to the Act of 1882. There was nothing in that Act which would authorise or empower the undertakers to break up any street which was not repairable by local authorities.

His LORDSHIP: Does the Act contain any definition of a street.

Mr. WALTER: Not the Act of 1908, but in the Act of 1882 they found a street described as any street, square, court, alley or thoroughfare within the area within which the undertakers were authorised to supply electricity either by Act or licence of the Board of Trade. London Bridge was, he urged, in a very curious position. It was the only bridge in London that was not a public street and the only one that was not repairable by a local authority. It was, in fact, the private property of the Corporation, and was entirely repairable by them. The defendants therefore had no powers in respect of it without the Corporation's consent—or without a special Act. That had been recognised by all other companies. The Corporation were perfectly willing to give any consent upon reasonable terms. On Sept. 14 last year defendant company served the Corporation as the local authority with notice that they intended to lay two high-pressure mains across London Bridge, and the Corporation, as the local authority, refused their consent. The company then referred the matter to the Board of Trade, who directed that the Corporation should be served with notice, and the trustees of the Bridge House Estate were, by order of the Board of Trade, subsequently directed to be served with a similar notice, and on the footing of the bridge being a street not repairable by a local authority. The Corporation having refused their consent to the opening of the bridge for the purpose of laying these mains the company thereupon memorialised the Board of Trade asking for their consent.

Mr. Justice PARKER: Do you say that the only powers they have is with regard to streets within their area of supply.

Mr. WALTER: Yes. The only area in London that was not within some area of supply was London Bridge.

Mr. Justice PARKER: And you say that the only powers they have are derived from reference to the previous Acts and they only apply to a street repairable by a local authority.

Mr. WALTER: They have a perfect right to get special powers.

Mr. Justice PARKER: You will have to go further, and show that they have no power to break up any street outside their area.

Mr. WALTER thought that was so. It was perfectly clear that the Acts referred to streets within the area.

Mr. Justice PARKER: Is not the meaning of this Act of 1908 that the scheduled companies can exercise outside their areas the powers that they had within the areas by their previous Acts?

Mr. WALTER: But they had no powers such as they were now claiming. It may have been that the Act was clumsily framed. If they got special powers they could do it, but they had not, and what was done there must be done either by consent or by special powers.

Mr. Justice PARKER: But by the Act of 1908 they have power to connect their generating station with their area of supply by a line running outside their area. If you are right, they cannot connect their two areas at all.

Mr. WALTER said that was so, but the difficulty only arose where the road was not repairable by a local authority. Why should these people have power to break up private property? There was no objection by the City: the real question was whether the company had power to do it without the consent of the Corporation, and in order to keep matters in *statu quo* until the whole matter could be determined he asked for an interim injunction.

Mr. BALFOUR BROWNE, K.C., for the defendants, said the powers the company contended for were contained in the Act of 1882. At the time these orders confined these undertakings to particular districts that the defendant company had got under certain orders districts on the north side and districts on the south side of the Thames. They were confined to those districts, and in them they could break up streets. If London Bridge had been within their area of supply they had an absolute right to break it up, though if it was not repairable by the public the company's powers were limited. Sec. 13 provides that "Nothing in the Act should authorise the breaking up of any street not repairable by a local authority except with consent or with the dispensation of the Board of Trade." If London Bridge had been within the company's area of supply, not being a street repairable by the public at large, the company would have had to get the consent of the London Bridge authorities or a dispensation from the Board of Trade. By the passing of the Act of 1899 the undertakers, under such superintendence as was thereinafter specified, had power to open and break up all the streets and bridges within the area of their special Act. "Limits of the special Act," he contended, meant any place where they had a right to break up a street, and was not merely limited to a place where they supplied. By those provisions the company had full powers to break up for the purpose of getting from the source of supply to the area of supply. The whole object of the Act of 1908 was to enable the company, amongst other things, to break up streets that were not within their area of supply. The object of the Act was to get rid of the disability. Either London Bridge was a street repairable by a local

Digitized by Google

authority, in which case the company had full powers to lay their mains, or if it was not the approval of the Board of Trade was required, and that had been applied for.

Mr. Justice PARKER, in delivering his judgment, said that the case raised a question as to the construction to be placed on sec. 4 of the London Electric Supply Act, 1908, an Act designed to confer further powers on London electric supply companies, of which the defendant company was one. Sec. 4 (1) of the Act provided for making (under agreement) a connection between the generating station or area of one authorised undertaking or specified company and the generating station or area of supply of another such undertaking or company. Sec. 4 (2) provided for such an undertaking or company making a connection between any two or more areas which it was authorised to supply, or between any such area and its generating station. It was obvious that under the old Acts the powers of companies were confined to their own areas. By sec. 4 (3) (*a*), as regarded electric mains, such an undertaking or company had, with respect to streets in any area which it was authorised to supply, the powers, and was subject to the provisions of the Acts and Orders relating to its powers of supply in that area. That provision was needed for the reason that the power to break up streets was for defined purposes only, and no existing undertaking had power to break up streets beyond its area of supply, and the provision extended the power to outside areas. By sec. 4 (3) (*b*) such an undertaking or company, with respect to streets, not with any area which it was authorised to supply, was to have the powers and be subject to the provisions of the Electric Lighting Act, 1882, and certain provisions of the Electric Lighting Clauses Act, 1899, and those provisions, so far as applicable, but subject to the provisions of sec. 4 of the Act of 1908, were incorporated with that Act, and were to have effect, and the authorised undertaker or specified company laying the mains was to be deemed "the undertakers." Again, that section conferred powers that were not existing before. The powers were given by reference to former Acts, and the section meant to apply the old powers to streets which were outside the area of supply. Sec. 12 of the Electric Lighting Act, 1882, incorporated certain provisions of other Acts, including provisions of the Gasworks Clauses Act, 1847, with reference to breaking up streets. But sec. 13 of the Act of 1882 placed certain limits on the exercise of those powers and provided that nothing in the Act or any incorporated Act should empower the undertakers to break up any street which was not repairable by the local authority, or any railway or tramway, without the consent of the authority, company, or person by whom such street, railway, or tramway was repairable, unless in pursuance of special powers, or with the written consent of the Board of Trade. Sec. 4 of the Act of 1908 gave power to the company to connect its northern and southern areas and to break up streets for that purpose outside its areas of supply. London Bridge was not a bridge which was repairable by any local authority, but by the Corporation (as trustees of the Bridge House Estates), and it was within sec. 13 of the Act of 1882 and a provision of the Act of 1899, and the company could not lay mains across it, except by the consent of the Corporation or the written consent of the Board of Trade. His Lordship made a declaration accordingly.

Valuation of Tramways.

In the Bill Chamber, Edinburgh, on Monday, before Lord Dundas, legal arguments were delivered upon an appeal of Glasgow Corporation against the valuation for 1910-11 of their tramways undertaking by the Assessor of Railways and Canals. The yearly rent or value of the undertaking has been fixed by the assessor at £278,070, and the Corporation asked that the valuation be fixed at £230,573. Hitherto the assessor, in making up the valuation (which he does on the "revenue" principle), has, in applying to the tramway undertaking sec. 3 of the Valuation of Lands (Scotland) Amendment Act, 1867, allowed as a deduction from the gross revenue not only one-half of the cost of maintenance of the permanent way and electrical equipment of the line, but also one-half of the sum annually set aside for renewal thereof. He now proposes to allow no deduction whatever in respect of renewal, but to continue to allow one-half of the cost of repairs. One-half of the sum set aside for renewal amounted last year to over £57,000, and appellants contend that the position now taken up by the assessor is unjustifiable. They urge that they are at least entitled to a deduction of one-half the expenses incurred in maintaining or repairing their permanent way, and charged to revenue in their published accounts, and that the practice initiated in 1873 should continue. On this basis the valuation would be £258,838. In the event of its being held that sec. 3 of the Valuation Amendment Act, 1867, does not apply to tramways, appellants submit that, looking to the nature of the undertaking, the whole expense of maintenance and repair is one which should fall not upon the landlord, but upon the hypothetical tenant, and as such should be a deduction before the valuation is struck. The deduction is in respect of repairs on (1) the causeway, (2) the rails, and (3) the overhead plant, &c. On this basis the valuation would be £230,573. In the event of a distinction being drawn between the larger and smaller repairs, appellants submit that they are entitled to the whole cost of the smaller repairs as a deduction before the valuation is struck, instead of only one-half of such smaller repairs as proposed to be allowed by the assessor. The valuation on this basis would be £269,059.

Mr. SPENS, for appellants, contended that with regard to the principle involved in undertakings such as that, which were profit-earning, it had been laid down in a series of decisions that appellants were entitled to a deduction in name of all expenses appropriately falling upon the tenant. His submission was that all such expenses—call them repairs or renewals—were expenses which appropriately fell upon the hypothetical tenant, and not upon the landlord. With regard to the statute, Mr. Spens submitted that, under the Valuation of Lands Act, 1867, the tramway undertaking must be held to be a railway, in which case appellants were entitled to deduction of half of the expenses referred to, because it had been laid down by the House of Lords that an exactly identical undertaking was a railway. Mr. Spens said that his Lordship and Lord Low had repeatedly laid it down in the Valuation Appeal Court that where no injustice followed in those cases they would not interfere with established practice. Since 1873 the practice contended for by appellants had been acted upon not only in Glasgow, but all over the country, and he submitted that there was no reason why it should now be disturbed.

Mr. GENTLES, for the assessor, said that renewals were properly landlord's burdens and not tenants', and, therefore, no deduction should be made in respect of them. He was applying to these charges the recognised principle that the obligation to maintain and to renew lay upon the landlord. There would always be the difficulty of deciding what were repairs and what were renewals, but he was prepared to admit that for the purposes of that case the entry contained in appellants' books under the head of repairs had been accepted by the railway assessor as representing repairs. He contended that inso far as those charges represented renewals the burden fell upon the landlord and not upon the tenant. So far as they were repairs the assessor had allowed one half of them on the ground that the tenants ought not to bear the cost of repairs due to traffic other than their own running. He knew of no case in which renewals as such had been recognised as a tenant's burden. The life of an average rail was between 12 and 14 years, but he differed from the argument that because the rails might perish, therefore the obligation to renew was a tenant's and not a landlord's burden. In such leases the tenant voluntarily subjected himself to the obligation to repair, renew and maintain. The reason for the insertion of such an obligation in the lease was that if it were not provided for in the lease, the tenant would not be under the obligation, because there was no such common law obligation upon the tenant, and there being no such common law obligation, that was why in valuations the Court had always applied the principle that renewal was a landlord's obligation. He argued from the fact that the obligation to renew was upon the tenant in the lease, that they were not, therefore, entitled to change the principle of valuation. All that was to be done was to take the obligation of the tenant into account as being a consideration other than rent. In the case of the Edinburgh tramways, which were at present under lease, the railway assessor did not take the rent stipulated in the lease as being the actual rent. He dealt with them very much as he dealt with the Glasgow tramways. He submitted that appellants' undertaking was tramway and not railway, and as such did not come within the scope of sec. 3 of the Valuation Act 1867.

Lord DUNDAS said he had formed an impression about the case, but in view of the importance of the questions raised and the amount of money involved, he would take a few days to consider his decision.

Electrical Co. v. Thomas, Son & Co.

The hearing of the above action was continued before the Official Referee (Mr. Pollock) during the week.

Mr. FRANCIS B. JOHNSON said that in Feb., 1906, he went to the Llynwi Valley mine on plaintiffs' behalf. He found the engine room was in an incomplete state, although parts of the machinery had arrived waiting to be installed there. He experienced difficulty in procuring labour. Witness explained how he erected the electrical plant. Common grease would be injurious to machinery of that sort running at such a high rate of speed—about 3,000 revs. per min. The oil supplied by defendants was dirty, thick oil which they were using on their old steam pump, and was not suitable for electrical machinery. On later occasions when witness visited the colliery, after defendants had been running the machinery, he examined the coils of the motor and found them in a very dirty condition and covered with oil. There was also a "short" on the motor owing to the windings having been burnt. The starter had also been broken, and the cable had been brought straight to the motor instead of through the starter. The short circuit was due to dirt, oil and dampness. The pump was not placed at a proper level and the trolley used for lowering it was not a proper one. The oil from the bearings ran down into the coils of the motor. Witness proceeded to rectify that state of things, and got the motor running by cutting out two of the coils which were burnt. It took him some two or three days to dry the motor out. Owing to the bad state of the brushes he was unable to get the exciter to work. When, however, he had cleaned them and put proper brushes on the motor he experienced no difficulty in getting the exciter to start. If the engine ran slowly it might prevent the exciter from exciting, but beyond that he could not think of anything which would account for its failure, except the negligence to the brushes, commutator, &c. When witness, in company with Mr. Blake, examined the exciter on June 17 they found it in a very dirty state, but having cleaned it they coupled up the machine in series and in parallel, and on both occasions they made it run satisfactorily. Witness further declared that the sump for the pump was not properly made, and that of itself did not give the electrical machinery a chance of life.

Mr. WM. A. SCOTT, electrical engineer, said he visited the mine and examined the plant. It was quite suitable for the purpose, but sufficient storage or sump room had not been allowed. The condition under which the plant was working, however, was the worst he had ever seen. The pipes too, were a poor lot, and so cramped was the room that the exhaust from the steam pump which was working at the time was blowing right on to the motor, and witness certainly would not have liked to have been responsible for running the motor afterwards. It was very necessary to have a man in charge of the plant who understood it.

The case had not concluded when we went to Press.

PARLIAMENTARY INTELLIGENCE.

BRADFORD CORPORATION BILL.

The tramway proposals included in this Bill, except the Laisterdyke route, which has already been sanctioned for the railless trolley system, have now been approved by Section B of the Local Legislation Committee of the House of Commons. In regard to the parcels clauses, the Chairman (Mr. C. N. Nicholson) said that they did not wish to limit the powers Bradford already had, and it appeared the Corporation already had the right to carry heavy goods and parcels over certain tramways. It was no part of the intention of the Committee to limit those powers. The Committee desired him to say that their previous decision was entirely based on certain parts of the official shorthand writer's notes, and in giving that decision they were under the belief that they were satisfying exactly what the Corporation were really asking for. The only question was whether it ought to be put right then or in the other House. He thought it best to make it there. "We make it perfectly clear, he added, "that the Committee were rather misled by the evidence given, and that under the circumstances they are prepared to give the Corporation powers to carry parcels over the whole of their tramway undertaking in the same way as is allowed in Manchester."

In regard to a clause dealing with the laying of electric cables and water mains along private streets, the Chairman intimated that the clause would be similar to the clause in the Oldham Act of 1909.

Electric Lighting Provisional Orders (No. 2) Confirmation Bill.—This Bill was read a first time in the House of Commons on Tuesday. The Bill incorporates provisional electric lighting orders relating to Ardrossan, Saltcoats and district; Cambuslang (extension); Cowdenbeath, Lochgelly and district; and Skelmorlie.

Middlesbrough Corporation Bill.—The clauses in this Bill relating to the gas and electricity undertakings were approved by Section A of the Local Legislation Committee of the House of Commons on Wednesday.

L.C.C. Tramways and Improvements Bill.—The Standing Orders Committee of the House of Commons have authorised the London County Council to insert an additional provision in this Bill to erect at the City end of the Victoria Embankment a weather shelter for tramway passengers.

All-Night Telephone Service.—The Postmaster-General (Mr. H. Samuel) informed Mr. J. Wood, in the House of Commons on Wednesday that the day and night service at present existing throughout the National Telephone Co.'s exchanges would be continued when the service was taken over by the Post Office.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

The Electricity committee of Salford Corporation invite applications from thoroughly experienced men, with first-class technical training, for the position of superintendent of the hired meter and testing department. Commencing salary £120, rising to £180. Particulars from the borough electrical engineer, Mr. Victor A. H. McCowen, Electricity Works, Frederick-road, Pendleton, Salford. Applications to the town clerk, Mr. L. C. Evans, by mid-day Monday, May 9. See also an advertisement.

A man is required to take charge of suction gas electric plant, accumulators, &c., on an estate in Herts. Applications to Estate Offices, Erpingham, Norwich. See advertisement.

A junior assistant engineer is wanted for an electric supply station near London. Salary 25s. per week. See advertisement.

A junior designer is wanted, with first-class college training and some years' practical experience in the design of d.c. and a.c. motors. See an advertisement.

There is a vacancy for a premium pupil at Watford electricity works. Applications to the Chief Engineer. See an advertisement.

The National Telewriter Co. (Ltd.), 30 and 34, Tabernacle-street, London, E.C., require telewriter instrument maintenance men for the provinces. See an advertisement.

An engineer, with good experience in the lay out and erection of electric winding engines, is required. See advertisement.

An inspector of telephones is required by the Government of Ceylon for an engagement of three years. Salary £200, and an allowance of R.6 per day to cover cost of subsistence when away from headquarters. Applications to Messrs. Preece & Cardew, 8, Queen Anne's-gate, London, S.W., by 30th inst.

A junior lecturer and demonstrator in physics is required at the University of Sheffield. Salary £150 per annum. Applications to the Registrar by June 1.

The following appointments have been made in connection with the West Ham electricity undertaking:—

Mr. F. J. Delves, motor superintendent, at £2. 10s. per week and commission at usual rates, in place of Mr. T. O. Wilton, resigned; Mr. J. Inglis, assistant motor superintendent, at £2 per week and commission, in place of Mr. W. L. Wreford, resigned; Mr. J. Turtle, lighting superintendent, at £2 per week and commission, vice Mr. A. S. Tong, resigned; Mr. E. E. Smith, as canvasser, at £1. 10s. per week and commission, in place of Mr. E. A. Broom, resigned.

The Tramways committee have appointed Mr. C. I. Baker (at present in the Newcastle-upon-Tyne tramways department) traffic superintendent of the Blackpool Corporation tramways.

Aberdare.—Sanction has been received to a loan of £16,797 for electricity supply, and last week the Council accepted tenders for generating plant, cables, &c., at £13,521.

Accidents in Mines.—On Monday a deputation representing the Parliamentary committee of the Trade Unions Congress, the Miners' Federation, Durham and Northumberland deputies, and the Enginemen and Wind Enginemen's Federation waited upon the Home Secretary (Mr. W. Churchill) to urge him to embody in a bill some of the recommendations suggested by the Royal Commission on Accidents in Mines.

Mr. James Rowe, of the Electrical Engineers' Society (Manchester), suggested the appointment of additional electrical inspectors, with practical working experience, and Mr. Enoch Edwards, M.P., urged the appointment of a new class of inspector, who would practically live in the pit.

Mr. Churchill, in reply, said he would give his best attention to the points raised. As they knew, a great bulk of the recommendations of the Royal Commission required legislation to give effect to them. In addition, the Commission had not finished its labours, and it would be much better that the bill for regulating the work of coal mines should be complete and comprehensive and should cover the whole ground. He was strongly of opinion that the inspectors should be strengthened, and if he remained responsible for the direction of the Home Office he should certainly make a request to that effect. He hoped it might be possible, in strengthening the inspectors, to do so with a proportion of men who had had practical experience in mines and who were possibly in some way in touch with the men. They were to have a conference with mine owners at the end of May, with a view to ascertaining how best to improve and systematise all rescue apparatus and work.

Asylum Lighting.—It has been decided to organise a bazaar to defray the cost of the proposed electric lighting installation at the County of Antrim Infirmary, Lisburn. The estimated cost of a complete lighting and power installation is put at about £1,000.

Australasia.—A firm in Wellington wish to get into touch with British makers of metal filament lamps and arc lamps of the latest pattern. Communications to H.M. Trade Commissioner, 9, Grey-street, Wellington (N.Z.).

On Feb. 28 the proposals with regard to subaqueous tunnels to connect the north and south sides of Sydney Harbour came before the Public Works committee, Sydney. The Royal Commission appointed in 1908 to deal with the subject recommended various schemes. Mr. Hutchinson, chief engineer of railway construction, has worked out an underground city railway scheme communicating with North Sydney, and the railway subway as described by Mr. Hutchinson will be a twin tunnel, each tube being a cast-iron shell of 18 ft. 8 in. internal diameter, 2 in. thick, and lined throughout with 1 ft. 1½ in. of concrete. The Commission proposes that this work should be first undertaken, and that electricity be used. Electrification of the North Shore railway is therefore involved, and the building of a power house. If this is done, it is probable that a city underground railway system proposed by Mr. Hutchinson would also be electrical. That is estimated to cost another £1,630,000. The chief railway commissioner reported that the chief engineer's estimate of £753,000 for the railway scheme was exclusive of electric power, rolling stock, &c.

A 1,500 kw. d.c. generator, supplied by Messrs. W. H. Allen, Son & Co. (consisting of Allen high-speed engine and General Electric dynamo) has been ordered by Melbourne Corporation. Condensing plant and an Edwards motor-driven air pump have also been ordered, and a new 15-ton overhead Chatteris crane is being put in to facilitate the erection of the plant. The new set is stated to be the largest of its kind in Australia. The demands upon the Corporation's electricity department are still increasing rapidly. 4,500 H.P. of motors (including 1,000 H.P. for new customers) are connected.

Bath.—The Council have adopted a recommendation of the Electric Light committee for substituting incandescent electric lighting for the present lighting in Pulteney-street and other districts.

108 metal filament lamps of 100 c.p. each are to be substituted for 10 arc lamps and for 54 gas lamps at a total annual charge of £522. 16s. 6d. (the amount now paid for lighting), and a capital outlay of about £200 for columns.

Battersea (London).—Mains are to be extended at an estimated cost of £125. Ten 200 c.p. metal filament lamps are to be provided and fixed for lighting Clapham Common (West Side).

Belfast.—The Harbour Commissioners have adopted a report recommending the execution of certain works for lighting the new graving dock by electricity and for the renewal of 15 lamps on Queen's Quay, Abercorn Basin, and Hamilton Graving Dock, at an estimated cost of £2,115. This is, however, subject to electric current being supplied by the Corporation at a cost not exceeding 1d. per unit.

Digitized by Google

Blackburn.—It is announced that there was a profit of about £1,000 on the electricity department for the past year and about the same amount on the tramways.

Brazil.—The electrification of the northern line of the Leopoldina Railway (from Rio de Janeiro to Petropolis) has been authorised.

East Ham.—An estimate of £2,674 for the duplication of the tramway track across Wanstead Flats has been passed by the Council.

Electrical Contractors' Association.—At the annual dinner of the Birmingham centre of the Electrical Contractors' Association on Friday

Mr. W. FINLAY (president), in proposing the toast of the Association, congratulated the members on the formation of the Midland section, which he understood was going strong and was doing good work for the trade. They had many interests to uphold and they needed co-operation for they had many battles to fight which necessitated combination. They desired to join with the manufacturers' associations, and to be dealt with in the same businesslike manner as they, as contractors, desired to treat their customers.

Mr. L. G. TATE, general secretary, responded, and referred to the general growth of the Association. During the past year something like 80 new firms had joined the association. That showed that they were growing, not in numbers alone, but in power. The central board was in negotiation with the Association of Municipal Corporations in order to see if they could arrive at an understanding in the matter of limiting the trading of municipalities to their proper functions. Let the municipalities have power to supply motors and electric apparatus on hire, but only on the understanding that the work should be done through the trade.

Fleetwood (Lancs.)—At the Council meeting last week the chairman (Mr. A. Swarbrick) said that, in regard to the electric lighting undertaking which the Council took over in September, everything in connection with it had been paid for, and the result of the six months' working to March was very satisfactory.

The revenue during the six months was £3,633 and the working expenditure £1,469. The gross profit was £2,164, interest on loans amounted to £382, and the sums to be charged out of revenue amounted to £766, making a total of £1,148. On the first six months' working, therefore, they had a profit of £1,000.

Fulham (London).—Experiments recently made by the borough electrical engineer (Mr. A. J. Fuller) near Avonmore-road with a new type of bracket lantern and grouped metal filament lamps have been successful and offer a very satisfactory and economical improvement upon the existing system of public lighting. It has, therefore, been decided that the whole of the lamps in that district shall be similarly fitted, and the alterations in those lamps already altered shall be made permanent at a cost of £32. 12s.

Hackney (London).—Electric supply mains are to be extended at an estimated cost of £554. 10s.

A communication has been received from London County Council in reference to the question of the period of electricity loans. The County Council note that the Borough Council has been able to set aside a reserve fund, of which the balance at March 31 last was £16,873, and observe that the Borough Council is repaying about 75 per cent. of its electricity loans on the system of equal instalments of principal, whereby the charge for interest diminishes each year, and it would, therefore, seem probable that the Borough Council would be able to transfer larger sums to reserve in the future. The County Council are convinced of the necessity of accumulating such a fund to a substantial extent when loans are running for 42 years, seeing that this period is admittedly much in excess of the useful life of the plant and machinery which represents a considerable part of the original outlay of electricity undertakings. It is suggested, however, that the Borough Council would be well advised, as an alternative to accumulating so large a reserve for renewals as is requisite to enable them to comply with the conditions on which the period of 42 years was sanctioned, to take steps to reduce, by agreement with the County Council, the period of the loans now running for 42 years to periods equivalent to the terms now allowed, had such periods been in operation since the commencement of the Borough Council's undertaking. It would then only be necessary for the Borough Council to accumulate a reserve fund to meet any extraordinary expenditure or to provide for such renewal of plant, &c., as might become necessary by reason of obsolescence before the expiration of the periods representing the probable life thereof. The Borough Council might consider, as a first step, whether they can arrange for the reduction of the period of loans sanctioned for plant and machinery for 42 years.

The Finance committee of the Borough Council, having consulted the Electricity committee, are of opinion that it would be inadvisable to reopen the question of loans the periods of which were sanctioned by the County Council.

The Electricity committee report having examined 11 tenders for 80,000 yellow flame arc lamp carbons, and the prices ranged from £5. 15s. to £4. 5s. per 1,000 pairs. The highest price in the past has been £3.12s.6d per 1,000. This rise means an increase of £50 per annum, or practically 10s. per lamp per annum. The committee decided for the present to instruct the Borough Electrical Engineer to buy in the open market from time to time to meet requirements.

Hampstead (London).—The Lighting committee have considered a report of Sir Alex. W. Kennedy on the financial and technical aspects of the electricity undertaking.

The committee are unanimously of opinion that the scheme recommended by Sir Alex. Kennedy should be carried out. At present they recommend that some of the existing plant be disposed of and that new plant be installed at an estimated cost of £8,515. The total expenditure would be £18,000 and an annual saving would be effected of £4,000. The money required would be borrowed from the reserve fund which now amounted to £45,000. The recommendation has been adopted by the Council and a number of tenders for the supply of the new plant have been referred to the committee.

Mr. Holtzapffel said that the committee had under consideration an amended offer from the Gas Light & Coke Co. for the improvement of the street lighting, but a motion that the work of transforming the gas lamps into electric lamps (already decided upon) be deferred until the amended offer be considered was negatived.

Holland.—Consul Turing (Rotterdam) states that the Peel Central Company has been formed at The Hague to erect works for supply of electrical energy for light and power in the provinces of North Brabant and Limburg. Turbo-dynamos will be employed, and turf will be used as fuel to commence with "and later gas refuse from a factory to be erected near the central station." It is calculated that electric light will be supplied at 40 per cent. less than in the large towns, and that electric lighting will be as cheap as petroleum lighting.

India.—"Indian Engineering" says 200 additional electric fans for the general offices of the N.W. State Railway at Lahore were purchased in India. Power for driving these will be supplied from the Lahore loco. shops.

A scheme for the general electrification of the Indian Midland Railway loco. and carriage shops at Jhansi has been sanctioned.

The administration of the Eastern Bengal State Railway are maturing a scheme for the electrification of the broad gauge workshops at Kanchrapara and the metre gauge shop at Saidpur.

Inquests.—An inquest was held on Saturday into the death of Henry Thomas Calladine, who was killed at Wingfield Manor Colliery on 20th inst.

Deceased's brother said he and deceased worked an electric coal-cutting machine. Witness felt an electric current pass through his body. He ran back from the machine, and at the same time heard his brother cry out. Witness stopped the machine, and, going towards his brother found him apparently lifeless, his head lying across the haulage rope. He obtained assistance, and resorted to artificial respiration until the arrival of Dr. Bingham, who pronounced life to be extinct.

By Mr. WALKER (Inspector of Mines): Witness did not examine the trailing rope of the coal-cutter before he started to work it. It was usual for the electrician to examine the cable and other electrical appliances. He did not know that by the rules the person in charge of the machine had to examine the trailing rope.

PERCY SMITH, assistant electrician, said he had examined the electrica parts during the shift, and they were all right. Since the accident he had made another examination, and he found a breakage in the trailing cable near where it was connected with the main cable. Perhaps the breakage was caused by a fall of roof. The result of that breakage was that the outer covering of the coal-cutter became alive. The system in operation at the colliery was quite safe, but it could be improved by the adoption of the plug system. The present system had not a very good earth. He found traces of fusing of the wires. His theory of the accident was that Calladine touched the haulage rope, which was in touch with the outer covering of the coal-cutting machine, which was alive.

H.M. Electrical Inspector of Mines (Mr. R. NELSON) said the trailing cable had become severed, with the result that the iron work of the machine had become alive. He believed that the cable strands had become broken by sawing movements. He suggested the plug system, which would be an improved connection for the trailing and the main cables, and with ordinary care fatalities of that kind would be very unlikely. Otherwise the system in operation was a good one.

The jury returned a verdict of accidental death.

An inquest was held last week on the body of Walter P. Liddell, who was killed at the power station of the Durham Collieries Electric Power Co., Philadelphia, on 15th inst.

Deceased was a joiner in the employ of G. Wardropper & Son, contractors, Penshaw, and was at the time of the accident engaged in doing some joinery work in the switchboard chamber of the power station when he came in contact with a live wire.

PERCIVAL H. ARCHBOLD, junior electrical engineer at the station, said he was in the switch chamber putting in a wood bush. Deceased was working in the chamber boxing part in with wood. Deceased was on the floor of the chamber and made a wooden wedge for witness, but this being too big he asked deceased to lessen the wedge, when witness then put it into its place with the bush. Just then there was a flash, which caused witness to drop from the switch on to the floor to get out of the way. Deceased dropped on to the top of a small wooden box from the metal casing, upon which he had been either standing or sitting. Mr. Wade, who was also there, caught deceased in his arms as he fell off the switchboard platform. They then carried deceased outside, and at that time he was alive. The chief engineer was informed, and meanwhile artificial respiration was being tried, and was continued until the

Digitized by Google

doctor arrived, about a quarter of an hour afterwards. Witness did not see deceased touch anything, and he could not explain how the accident happened, the putting in of the wedge having nothing to do with it. He knew there was danger in spite of the fact that the conductors were supposed to be insulated. The charge engineer (Mr. Pyle) warned deceased that there was danger. Current at 5,750 volts was passing through the conductors. The conductors were quite distinguishable from the surroundings. Witness was told to keep an eye on deceased because there was danger there of which deceased had not expert knowledge and would not recognise it.

JOHN S. WADE, junior electrical engineer, said he walked into the switch chamber about 11:15 on the date of the accident, and saw a flash. Deceased was standing on the box leaning against the metal casing with his right arm at the back of the conductors, and was drawing his hand away when witness noticed him. There appeared to be a few sparks passed between his fingers and the conductor as he was drawing it away. Deceased sank down on the wooden box, making some exclamation of surprise, and then collapsed. Deceased got an electric shock, which he believed was caused by the breakdown in the insulation of the conductor. He thought there was some flaw in the insulation of the conductor at that particular place. Otherwise the accident would not have happened. Deceased had nothing in his right hand at the time.

FERDINAND F. PYLE, engineer-in-charge at the time of the accident, said there were three conductors in the switch chamber, side by side, insulated with a special insulation of mica wrapped around with Empire tape, which was coloured yellow. The work was done about five weeks ago by an electrical firm. The insulator would withstand a voltage of 12,000, or about double the working pressure; it was tested under pressure for that amount. He warned deceased about half-an-hour before he proceeded to the chamber not to touch the insulator, which he appeared to understand perfectly. Deceased had not been in that chamber before, but had done similar work in another exactly like it. There would be no danger in fixing the casing round the conductors. After the accident witness examined the chamber, and found signs of burnt skin upon the edge of the metal casing, and there was also a slight burn on the tape of one of the conductors, and it could be seen that the shock had been got from that point. Witness told deceased distinctly that a slip of a chisel on to a conductor would kill him, and witness had repeatedly warned him which parts not to touch—those that were coloured yellow. Dampness in the atmosphere would make all the difference to the insulation.

A verdict of accidental death was returned.

Institute of Chemistry.—A revised edition of the Register of Fellows, Associates and Students of the Institute of Chemistry of Great Britain and Ireland (30, Bloomsbury-square, London, W.C.) has just been issued, and contains, in addition to the lists of fellows, &c., an outline of the regulations for admission to the Institute, abstracts from the charter and by-laws, comittees for 1910-11, &c.

Italy.—The Soc. Elettrica Comense A. Volta have obtained a concession for the construction and working on the overhead system of a metre gauge electric railway from Como to Cernobbio.

M. Consul de Zuccato states that, so far as he is able to judge, most of the electrical equipments in mills and factories in the Venice district are of foreign manufacture, but he believes there is now an advance in the manufacture of such apparatus in Italy, and some foreign firms have opened offices and workshops in that country.

The hydro-electric works at Ponte della Serra, near Feltre, are approaching completion, and are expected to start working this year. The capacity of the plant will be 9,000 H.P., and extensions to increase the capacity to 15,000 H.P. will probably be commenced next year. The Edison, Adriatica and Cellina Companies are interested in the venture, and Signor Quarisa is the engineer responsible for the equipment.

The first part of the hydro-electric plant of the Societa Bellunese per l'Industria Elettrica, on the river Ardo, has recently been finished. The alternators at the generating station in the Vezzano valley are driven by two 300 H.P. turbines supplied by a Milan firm.

The Cellina Co. propose to utilise the water-power of the river Piave and the lake of Santa Croce (Belluno) for the generation of electric power. The scheme provides for three generating stations of an aggregate capacity of 14,000 H.P., at the foot of the Belluno Pre-Alps, at San Floriano and at Castelletto.

The hydro-electric plant erected by Signor Milani at Bassona (Verona) was completed and started working in Nov., 1909. The plant includes five turbines of an aggregate of 10,000 H.P. and Westinghouse generators. On a portion of the transmission line the voltage is 40,000.

Japan.—The South Manchuria Railway Co. are floating a loan of 40,000,000 yen (£4,083,000) of which 1,000,000 yen (£102,07) is for an electric power house at Dairen, 500,000 yen (£51,037) for an electric tramway at Dairen, and 300,000 yen (£30,622) for electric lighting plant at various places.

Lancaster.—A long discussion took place at the Council meeting on Wednesday on the question of tramway fares, and ultimately, on the recommendation of the Tramways committee, it was decided to adopt a universal penny fare.

Leek.—In future the Lighting committee will have control of the electricity and gas undertakings.

Leicester.—On Tuesday the Tramways committee reported to the Council that in their opinion immediate steps should be taken for providing additional generating plant at the tramways power station, having regard to the rapidly-increasing demand for the supply of electrical energy for power, and they recommended the installation of a 1,000 H.P. turbine engine, the enlargement of the existing engine house, the provision of two additional boilers, and further condensing plant and feed pump. The estimated cost of the proposed additions is £19,190, and application is to be made for sanction to a loan of that amount.

The committee have had under consideration the question of reducing the charges for the supply of energy for power, and they recommended that the basic charge (15s. a quarter per horse-power of the maximum power demanded by the consumer) should be reduced to 10s. a quarter per horse-power, the charge per unit to remain at ¾d., as at present. The scale of discounts allowed upon the units consumed is to be extended.

The recommendations were adopted by the Council.

London County Council.—On Tuesday Mr. Hayes Fisher, in introducing the estimates of income and expenditure for the financial year 1910–11, said that the only undertaking from which relief to rates might some day be obtained was the tramways.

According to the estimates, the financial position of that undertaking was extremely satisfactory. After providing for working expenses and debt charges, there was expected to be a surplus for the year of £244,132. Under a resolution of the Council passed in June of 1908 £125,989 of the surplus would be carried to renewals fund and £118,142 to general reserve. If the estimates were realised the balances on those two funds taken together would amount to nearly £700,000 by March 31, 1911. No doubt in the near future the renewal fund would be called upon to meet heavy expenditure on renewals, and indeed the whole of the fund must be regarded as required sooner or later for that purpose. The general reserve fund was on a different footing, and the Council would have to consider what limit might fairly be put on that fund. So far as he could see, he did not think the question of allocating money to relief of rates was likely to come up for consideration during the lifetime of the present Council. In saying that he did not wish to leave the impression that the tramway undertaking was not in a flourishing condition. On the contrary, he was convinced that its financial condition was entirely sound.

Highways Committee's Report.—The whole of the report of the Highways committee was opposed and stood over for a week. Amongst the items included was that tenders be invited for the supply of 250 electric cars; the acceptance of various tenders; and a recommendation that no objection be offered to the proposals of the St. James & Pall Mall Electric Light Co. to declare the pressure at which it supplies energy at 110 to 220 volts to those consumers with whom it has already been arranged or may arrange to supply at such pressures on the understanding that any variation shall be within the 4 per cent. on that 107 and 214 volts respectively prescribed by the regulations of the Board of Trade.

Luton.—The time for completing the unconstructed portions of the Council's tramway scheme has been extended by the Board of Trade until Aug. 11, 1912.

Marconi Trans-Atlantic Service.—The new service between Clifden and Glace Bay was opened for traffic on Saturday. It is announced that a continuous day and night service is now maintained for commercial and other purposes.

Obituary.—The death is announced of Sir Owen R. Slacke, chairman of the Kent Collieries Corpn., the Bogota Telephone Co. and other companies.

The death of Commander Reginald Freeland Yonge took place at Fursdon, near Plympton, Devon, on Monday. Deceased entered the navy as a cadet in Dec., 1863. In March, 1865, he served on the "Terrible" (under Capt. Napier, and later Capt. J. E. Commerell, V.C.), then engaged in laying the Atlantic cable in company with the "Great Eastern." Having lost the cable, the "Terrible" made a trip to Malta and then back again, laying cable with the "Great Eastern."

Personal.—Mr. J. C. D. Denison-Pender has been elected vice-chairman of the Stores and Contracts committee and a member of the Accommodation and Attendance and the Books and Apparatus sub-committees of the Education committee of London County Council.

Presentation.—On 22nd inst. Mr. Edward Marett, chief of the submarine cable department at the British School of Telegraphy, was presented by the staff and students with a travelling bag with silver fittings on his retirement to take up an appointment with the Pacific Cable Board. The manager of the school (Mr. Arthur W. Ward) made the presentation.

Radcliffe.—The Board of Trade inquiry by Mr. A. Read into the application of the Lancashire Electric Power Co. for a provisional order for supplying electricity within the area of Radcliffe Council was concluded last week, when the inspector sat specially to hear the addresses of the legal representatives of the various parties. The evidence taken at the inquiry was set out in our issue of April 15.

Rubber Boom and the Electrical Industry.—Mr. G. Basil Barham, A.I.E.E., contributed to the "Financial Times" of the 23rd inst. some notes on the effect of the rapid rise in the price of rubber on the electrical industry. Mr. Barham is, speaking generally, of opinion

Digitized by Google

that the increase in price will not seriously affect the industry, which is in a position to adopt reliable and cheaper substitutes for the chief purposes for which rubber is used in connection with electrical operations.

Russia.—A correspondent of the "Financier" says that public works on a large scale will be started at Vladivostock during the current year, and that tramways and electric lighting are in the programme.

The British Vice-Consul at Baku (Mr. A. E. R. McDonell) states that Baku Municipality have raised a loan of 27 million roubles (about £2,848,500) for, inter alia, electricity supply, electrification of the tramways and other works. About 960 arc lamps will be required for public lighting, but the municipal authorities have not yet decided whether they will establish their own electric power station or come to an arrangement with the existing power company.

Sheffield.—The new tramwaymen's club was formally opened by the chairman of the Tramways committee, Sir Wm. Clegg, on Tuesday.

The general manager of the tramways, Mr. Fearnley, said there were now 1,050 members, and the main object of the club was to provide good meals at a low price. The Tramways committee paid the wages of all engaged in the club, to which there were benevolent and hospital funds attached.

Siam.—The report of Acting Consul Dunn on the trade of Bangkok for 1908-9 issued this month (April) states that the new telephone system in Bangkok will shortly be opened. The imports of electrical goods at Bangkok port during the year ended March, 1909, were valued at £62,300, compared with £23,513 and £8,732 in the years ended March, 1908 and 1907 respectively. Of the first-mentioned amount 37 per cent. was from the United Kingdom, 26 per cent. from Germany and 17 per cent. from Sweden.

Summer School Lectures.—Glamorgan Education committee have arranged short summer courses of lectures during August, as follows: (1) Practical surveying course at Penarth; (2) Engineering course; Mining, mechanical and electrical engineering (laboratory work) and practical mathematics; (3) Metallurgy course: Metallurgy, chemistry and practical mathematics; (4) Teachers' course: Geology (lectures and field work), physics and chemistry (this course has been arranged to meet the requirements of teachers engaged in or preparing for technical work at evening schools or technical schools); (5) Evening lectures for colliery firemen on explosives and shot-firing; (6) Evening lectures on electricity in mines. Courses 2, 3, 4, 5 and 6 will be held at University College, Cardiff, the other courses at the County School, Penarth. Certificates will be issued to successful candidates. Particulars and admission forms from 35, Park-place, Cardiff.

Switzerland.—A committee represented by Messrs. Dufour Freres, of Les Avants, have obtained an 80-year concession for an electric funicular railway from Les Avants to Sonloup.

Tramway Transfer.—Audenshaw Council give notice of intention to lease the tramways in the district to Manchester Corporation until April 1, 1924.

The rent to be paid annually for the Audenshaw-road tramway will be on a gradually descending scale from £595. 13s. 1d. as on Oct. 1, 1909, to £317. 16s. 4d. on April 1, 1924, and for the Manchester-road and Droylsden-road tramways £1,662. 17s. 11d. as on Dec. 1, 1904, and on a gradually descending scale from £646. 2s. 2d. as on June 1, 1905, to £594. 6s. 2d. on June 1, 1923, 10s. on Dec. 1, 1923, and 5s. on April 1, 1904. The lease contains provision for the electrical equipment of the tramways.

Venezuelan Telegraphs.—Mr. C. H. de Lemos, British Consul at Ciudad Bolivar, in reporting on the trade of that district for 1909, makes the following comments concerning matters telegraphic:—

Telegraphic cable communication with other parts of the world was re-established in May by the reopening of the French cable service, which had been closed for a number of years. The service is rapid and reliable. Lately, however, a regulation has been enforced by which a translation of all messages in code or cypher has to be supplied by the sender to the telegraph office, without which the cable is not forwarded. This rather vexatious regulation checks the use made of the French cable service, especially from inland towns, as senders are loth to furnish these translations, which may contain trade secrets or other confidential matter. Consequently many people and firms still prefer to send their cable messages by mail to Trinidad, to be despatched to their destination by the West India & Panama Co. without translation.

Watford.—The Council have approved terms submitted by the electrical engineer (Mr. F. W. Purse) for supplying energy to the L. & N.W. Railway, subject to an agreement being entered into providing for a minimum payment of £500 per annum for seven years.

West Ham.—A wing is to be added to the Greengate-street car depot.

The electrical engineer (Mr. Couzens) reports, in regard to the additional generating plant required, that it will be necessary to put in hand some of the work as soon as possible. The turbo-alternator is under discussion with the Westinghouse Co. and it is suggested that tenders be obtained for condensing plant to be used in conjunction. It is also advisable (Mr. Couzens considers) to proceed with the boiler and switchgear at an early date. The cables for the Stratford and Silvertown schemes are included in the existing contract with the British Insulated & Helsby Cables, and these should be put in hand as soon as convenient. Mr. Couzens has been authorised to negotiate for renting a site for a sub-station in Chapel-street, and to obtain quotations for the plant mentioned by him.

In regard to the terms for the new Rateau turbine set by the British Westinghouse Co., the engineer has had further communication with the company as to the payment to be made by them for the excess steam used by the existing turbo from the date of the tests in October to the agreed date when the new turbo is to be installed. He has agreed with the company for £250 (£100 in cash and £150 to be deducted by the Council from the first instalment due to the company).

Westminster.—The contracts for the supply of electricity to the Council's buildings expires on June 24, and the Town Clerk has been instructed to negotiate for the renewal of the contracts on the same terms as at present—viz., Metropolitan Electric Supply Co., 2½d. per unit for lighting; St. James & Pall Mall Electric Light Co. and Charing Cross, West End & City Electricity Supply Co., 2d. per unit for power.

Wireless Telegraph Notes.—British Consul Reed, discussing the subject of wireless telegraphy in the Azores, reports that the radio-telegraphic stations at San Miguel, Sta. Maria, Fayal, Flores and Corvo were completed early in 1910, and are now open for the service of the public.

An interesting example of the utility of wireless telegraphy is shown in an announcement that on Wednesday last week a message was sent from a Marconi installation of one of the Cunard liners in mid-Atlantic to the Haymarket Theatre, London, booking four stalls for the performance of "The Blue Bird."

There is another Australian aspirant for fame in connection with wireless transmission. Mr. Reginald Wilkinson, who is described as a young Australian, is reported to have discovered a process for transmitting pictures by wireless transmission, and also an improved process for the same over ordinary telegraph wires. Practical demonstrations of Mr. Wilkinson's work are stated to have appeared in the Sydney "Telegraph" of April 25.

Electro-Harmonic Society.—The annual general meeting of this society will be held on Tuesday next (May 3) at 4:30 p.m. at the Institution of Electrical Engineers, 92, Victoria-street, Westminster. During the past season 74 new members were elected, 3 members were lost by death, 42 resigned and 23 have been struck off for non-compliance with rule 11, a net gain of 6 members, bringing the total to 632. The accounts show surplus assets to date £70. 19s. 1d., against a balance forward of £63. 19s. 3d. The total receipts from subscriptions, entrance fees and extra concert tickets were £355. 12s., against an expenditure of £360. 9s. 2d. Cash in bank and in hand is £59. 2s. 1d.

The Osram Dinner.—The annual dinner of the staff of the Robertson and Osram Lamp Works at Hammersmith took place on Friday evening last. The function was as successful as is usually the case, and business was entirely put on one side. In proposing the toast of the allied firms, Mr. Wilson, who presided, drew attention to the way in which the lamp output from the Hammersmith works had increased in the last few years, and how such development was of distinct advantage to Hammersmith Corporation, as, apart from paying the rates, more than £6,000 was expended by the company on electrical energy alone. The toast was replied to by Mr. Hirst.

"Tantalum" Athletic Club Concert.—The first annual concert of the "Tantalum" Athletic Club (connected with Messrs. Siemens Bros.' Dalston works) was held on Monday evening, when an interesting programme was arranged.

The hall was illuminated by "Tantalum" and "Onewatt" lamps, which shed their brilliance on the "brilliant passages" of the artistes. Invitations were limited to employés of the firm, and there was a good muster. The talent also was entirely from the works staff, and the enjoyable items rendered proved that there was no limit in this respect. Miss Harrison (pianoforte), Messrs. McFarlane, Dennison and Hicks (baritones) and Mr. A. E. Watts (humorous) distinguishing themselves. A novel feature was a singing competition (open to all employés of the firm), for which prizes were offered, the audience acting as judges. The first prize went to Mr. Rodgers, the second to Mr. Lewis and the third to Mr. Hopper, jun. Miss Sabourin, Miss Crisp, Miss Clark, Mr. C. D. Gray, Mr. Gingell, Miss Wade (violin), Miss Topper, jun., and Miss Coutts (elocutonists) also competed. Competition proved very amusing, and brought out much latent talent, promising well for many more enjoyable evenings to come. We must not omit to say that Messrs. Jarvis and Lucken and Messrs. Collins and Pryor (the latter pair at the piano) were in good form. The proceeds go to the war chest of the newly-formed "Tantalum" Athletic Club

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are invited up to June 14 for supply of 100 party line common battery telephone wall sets, 10 party line common battery table sets, 100 switches, common battery, single extension and intercommunication, and 3,000 telephone protectors to the Postmaster-General's department in VICTORIA. Tender forms and specification at the Commonwealth office, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited (up to May 17) for supply to the Postmaster-General's Department, VICTORIA, of 50 coin attachments. Tender forms and specifications from the High Commissioner's Office, 72, Victoria-street, London, S.W.

Tenders are invited up to June 7 for supply of one frame, main distributing, to the Postmaster-General's department in WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W. See also an advertisement.

The Postmaster-General of the Commonwealth of AUSTRALIA requires tenders up to May 17 for supply of 2 tons of wire, twisted pair, outside distributing, No. 16 Legal S.W. gauge. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to June 8 for the supply of protectors, switchboards (small) and common battery telephones to the Postmaster-General's Department, QUEENSLAND. Tender forms, specifications and general conditions may be obtained at the Commonwealth offices, 72, Victoria-street, London, S.W. See also advertisement.

Tenders are required by June 8, 1910, for the supply of six sections of common battery switchboard and equipment jumper wire and cable to the Postmaster-General's department in QUEENSLAND. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W.

Tenders are invited, up to May 18, for the supply of paper insulated lead-covered and brass ribbon taped cable to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to June 1, for the supply of eight sections of common battery switchboard to the Postmaster-General's Department, NEW SOUTH WALES. Tender forms, specifications, and general conditions may be obtained at the Commonwealth offices, 72, Victoria-street, London, S.W.

LITTLEBOROUGH Urban District Council invite tenders for the supply and laying of h.t. feeder cables, l.t. distributors, roadwork, &c., for private lighting, and transformer kiosk, with transformers and equipment and switchgear in substation. Copies of specification, forms of tender, &c., may be obtained from the clerk to the Council, Mr. Geo. H. Wild. The works are to be carried out in accordance with plans and specifications, which may be seen at, but not obtained from, the offices of the consulting engineers, Messrs. Hawtayne & Zeden, 9, Queen-street-place, London, E.C., from whom further information can be obtained. Tenders to the Clerk to the Council, Council Offices, Littleborough, near Manchester, by May 2

NEWPORT (Mon.) Electricity committee invite tenders for supply and erection of a 1,000 kw. double-current turbo-generator or, alternatively, a 1,000 kw. or 1,500 kw. turbo-alternator, together with surface condenser. Specifications, general conditions and forms of tender from the borough electrical engineer and tramways manager (Mr. H. Collings Bishop). Tenders to the Town Clerk by first post Monday, May 2.

LEEDS City Council invite tenders for supply of 5¼ miles of 0.15 sq. in. three-core cable, suitable for working pressure of 6,600 volts. Tenders to the town clerk (Mr. Robt. E. Fox), by 10 a.m. Monday, May 9. Specifications and conditions from the manager of the electric lighting department (Mr. H. Dickinson), 1, Whitehall-road, Leeds.

WEST BROMWICH Electricity committee invite tenders for supply, delivery and erection of a 750 kw. d.-c. turbo-generator and surface condenser. Specification, general conditions, forms of tender, &c., from the borough electrical engineer (Mr. W. A. Jackson), Electricity Works, West Bromwich. Tenders to the Chairman of the Electricity committee, Town Hall, West Bromwich, by May 2.

The SECRETARY OF STATE FOR WAR invites tenders for the supply of two plants for the production of hydrogen and oxygen by the electrolysis of water at the Balloon Factory, South Farnborough, Hants. Forms of tender from the Director of Army Contracts, War Office, Whitehall, London, S.W., where tenders are to be delivered by noon of May 4.

DUBLIN Technical Education committee want tenders by noon May 11 for wiring the technical schools, Bolton-street, Dublin. Specification from the City Electrical Engineer, Fleet-street, Dublin.

WHITEHAVEN Corporation require tenders by mid-day May 2 for supply of a Green's fuel economiser and pipework and main switchboard. Specifications from the Borough Electrical Engineer.

GLASGOW Corporation want tenders by 10 a.m. May 5 for one year's supply of coal to their electricity generating stations (about 100,000 tons). Forms of tender, &c., from the City Electrical Engineer.

The Deputy Postmaster-General, MELBOURNE, will receive tenders until 3 p.m. May 17 for supply of 1,010 reinforced concrete telegraph poles, preferably of Australian cement. Local representation necessary. Specification from Commonwealth office, London.

LAUNCESTON (Tasmania) City Council want tenders by 4 p.m. June 13 for overhead equipment for electric tramways, and by 4 p.m. June 27 for supply of synchronous motor generators and battery, reversible booster, &c. Specifications, &c., from the Town Clerk, on deposit of £1. 1s.

The Electric Light committee of PRINCE RUPERT (British Columbia) require tenders by noon May 3 for supply of boilers, engines, condenser pumps and piping, and electrical apparatus. Specifications may be seen at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

West Ham Council have accepted the following tenders for electrical supplies:—

British Thomson-Houston Co., house service a.c. wattmeters (new type of meter); W. Lucy & Co., house service cut-out boxes; Pirelli Limited, indiarubber-covered wires and cables (six months, with option of extending for further six months); Baxter & Caunter, British Electrical Mfg. Co., Feld Bros. & Co., J. H. Tucker & Co., Falk, Stadelmann & Co., General Electric Co., Edison & Swan Co., Siemens Bros. Dynamo Works, Siemens Bros. & Co., British Westinghouse Co., E. Dewhurst, W. T. Glover & Co. and Accles & Pollock, electrical accessories.

West Ham Council have also accepted the tender of Blakeborough & Sons at £486 for circulating water piping.

London County Council have received the following tenders for supply of watt-hour meters for the central car repair depot, car sheds and sub-stations:—

Electrical Co. (*rec. for accep.*)..... £364. 9s. and	£389	12	0
Ferranti Limited	544	12	9
General Electric Co.	450	12	0
British Thomson-Houston Co.	422	19	9
Bat Meter Co.	372	5	0

East Ham Council have accepted the tender of Pollock & McNab for a motor-driven drilling machine with motor and set of twist drills at £84. 6s.; of Baxter & Caunter for supply of cable; that of the Patent Railway & General Eng. Co. to affix 100 patent manganese steel plates to the rail joints at 35s. for each joint exclusive of unskilled labour; and that of Hadfields (Ltd.) for manganese steel rails for a double curve at £280.

Belfast Harbour Commissioners have accepted the following tenders:—

Hind Bros. & Co., castings of bases for electric light masts; James Allan (sen.) & Son, tubular electric light masts; Stanley Johnston, arc lamps.

The Highways committee of London County Council recommend for acceptance the tender of Buck & Hickman for machine shop equipment of the central car repair depot at £2,949. 7s. 6d. The chief tramway officer's estimate was £3,000.

Aberdare Council have accepted the following tenders: D. T. Davies, electricity station buildings, £1,085; Lancashire Dynamo & Motor Co., generating plant, £3,312; Callender's Co., cables, £8,247.

Salford Education committee have accepted the tender of the Northern Electrical Co. for wiring the Wellington-street schools at £133. 13s.

Smethwick Education committee have accepted the tender of Best & Lloyd for the supply of electric light fittings for the technical school, and that of J. Ludlow for wiring work at £79. 15s.

For the ninth successive year the Lancashire Dynamo & Motor Co. have received the contract for high and low-speed motors (20–50 H.P.) for Salford Corporation.

The Midland Railway Co., who have decided to extend their electrical generating station at Derby, have placed an order for two 1,250 kw. Willans "impulse disc and drum" type turbines.

Woolwich (London) Council have accepted the tender of Crompton & Co. for supply of A type carbons at £54. 11s. 3d.

Faversham Council have accepted the tender of J. Smith for a Phœnix bitumen boiler.

Digitized by Google

Bedford Council have accepted the tender of W. H. Allen, Son & Co. for a 750 kw. steam alternator at £3,706.

Slough Council have accepted the tender of the local electric light company for lighting the public hall clock.

Battersea (London) Council has accepted the tender of W. Geipel & Co. for annual supply of arc lamp carbons.

Aylesbury Council have accepted the tender of E. T. Mackrill & Sons for electrical work for a year.

BUSINESS NOTICES.

By mutual agreement Messrs. James T. Donald & Co., 35, McAlpine street, Glasgow, have relinquished their Scottish representation of the Union Cable Co. in favour of Messrs. J. C. Fisher & Co. Mr. J. C. Fisher, who has had the management of Messrs. Donald's electrical department for the past seven years, has now opened offices at York-buildings, York-street, Glasgow, where all inquiries and orders for electric wires and cables should now be sent, and where stocks will be available.

Messrs. Ronald Johnstone & Son, mining and consulting engineers, 190, West George-street, Glasgow, have opened a London office at 60, London-wall, E.C.

Plant for Sale.—Eastbourne Corporation advertise for sale a 50 kw. steam alternator. Particulars from the borough electrcial engineer, Mr. J. K. Brydges.

For Sale.—In another column an electric light and power undertaking is advertised for sale as a going concern.

Factory Premises to Let.—Messrs. Rowlandson & Co., 267, Mare-street, Hackney, London, N.E., advertise some factory premises to let

"The Journal."—Part 200 of the "Journal" of the Institution of Electrical Engineers is now ready, price 5s. Particulars of contents are given in an advertisement.

Shakespeare Festival.—The electrical engineer is interested, with the general public, in the dramatic and social events of the time. Year after year the Shakespeare festival at Stratford-on-Avon grows in importance and covers a longer period—this year from April 22 to May 14—when Stratford-on-Avon gives itself up to Shakespeare's plays. To enable lovers of the "Sweet Bard of Avon" who reside in the Metropolis to visit the scenes of many of the plays the Great Central Railway Co. have arranged a convenient service of express trains by their short route, and cheap tickets at the fare of 6s. 6d. return are issued from Marylebone several days during the week. The arrangements are specially suitable for attending the matinee performances in the Memorial Theatre on April 30, May 2, 3, 5, 7, 10, 11, 12 and 14, visitors being able to return in good time the same evening.

Technical Literature.—The Hill Publishing Co. (Ltd.), of 6, Bouverie-street, London, E.C., and of New York and Berlin, who are the sole agents for the McGraw-Hill Book Co., of New York, have ready a catalogue comprising a large number of electro-technical and other books. Copies of this catalogue can be obtained on application, and the company's publications can be consulted at the London offices.

CATALOGUES, &c.

Installation Accessories, &c.—Messrs. Siemens Bros. Dynamo Works have just issued a number of new price lists dealing with installation accessories and conduits. Consulting engineers, wiring contractors and others interested in this class of work should provide themselves with copies of these lists. Messrs. Siemens feel confident that the quality and prices of their material will bear comparison with any other on the market. Delivery can be effected immediately from stock, an advantage which should not be overlooked.

Crane Specialities.—The Witton-Kramer Electric Tool & Hoist Co. forward leaflets dealing with electric lifts and magnets, electric hoisting appliances and electric tool equipments. Complete catalogues will be ready shortly.

Precision Instruments.—Messrs. Isenthal & Co. have ready a description of an aperiodic millivolt and ammeter for continuous and alternating current which works on the Deprez-Weston principle. It is fitted with two scales, one for use with continuous current and the other for alternating current, between which, it is claimed, there is perfect accord.

"The Place of the Battery in Power Station Design."—The D.P. Battery Co. have sent us an artistically arranged pamphlet with this title. The question of the way in which the battery can be used to assist the generating plant is discussed, the costs being made out for the two cases when this class of apparatus is employed in stations having both light and power loads. This company have supplied batteries for use in connection with power work, and there is no doubt that its employment will be found equally economical for colliery plants, &c. All who are interested in battery work should obtain a copy of this booklet.

A.E.G. Steam Turbine.—The A.E.G. Electric Co. forward a pamphlet containing a complete account of the construction and operation of this turbine. This pamphlet will be of general interest. Combined turbo-generating sets are made by this firm with capacities so widely differing as 2 kw. and 15,000 kw.

BANKRUPTCIES, LIQUIDATIONS, &c.

Robt. Edwin Jay (trading as the Bristol Electrical Co.), 143, Cheltenham-road, Bristol, has been adjudicated bankrupt.

The trustee (Mr. F. Stone, 47, Full-street, Derby) in the bankruptcy of Lancelot W. de Grave, electrical engineer, 19, Queen-street, Derby, has been released.

The Grasse & Cannes Electric Tramways Synd. (Ltd.) is being wound up voluntarily. A meeting of creditors will take place on May 3 at Mr. H. R. Green's, liquidator, 37, Conduit-street, London, W.

A meeting to receive an account of the winding up of the Accumulator & Motor Construction Co. (Ltd.) (in vol. liq.) will be held on May 31 at Mr. Jesse Smith's, 79, Queen-street, London, E.C.

Bankruptcy Notice.—At the instance of S. R. Barley, 52, Castlenau-gerdens, Barnes, and H. H. Syms, 8, Kenilworth-court, Putney, a bankruptcy notice has been issued against Frank Sheppard, electrician, 4, Haslett-road, Kensington, London.

COMPANIES' MEETINGS AND REPORTS.

Indo-European Telegraph Co. (Ltd.)

The forty-third ordinary general meeting of this Company was held on Wednesday, Mr. J. Herbert Tritton in the chair.

The SECRETARY (Mr. John I. Bethell) read the notice convening the meeting and the auditors' report.

The CHAIRMAN said: Gentlemen, I am able to say that the year under review has been an uneventful one. Persia has reverted to a more or less normal condition from the telegraph point of view, and our lines over the great portions of the continents of Europe and Asia traversed by the Company's system have been subject to even less interruption than in former years. Strange to say, our troubles this year have been nearer home. The difficulty of the interruption of submarine cables owing to damage done by the trawls of the fishing fleets round the coasts of Great Britain is one that has seriously affected most of the companies having cables touching these shores. It is, of course, a serious difficulty, and one that certainly calls for solution. In these days, when the merchant entrusts the safety of his Argosies and even perhaps his commercial credit to the difference between a Morse dot and a dash over many thousands of miles of wire, telegraphic communications must be not only the best that can be given, but must be so far as possible completely secured against extraneous risks of all kinds. Both the cables across the North Sea in which the Company has leased wires were totally interrupted, the one for 79 days and the other for 66 days, of which 49 days were concurrent. The effect of this on the Company's business may well be imagined, particularly as the Postmaster-General found himself unable, owing to the requirements of his own traffic, to give us the use of relief wires except for a very small portion of the time. Under the above circumstances the Directors have been forced to look for additional cable accommodation between England and Germany, if possible in a direction removed from fishing operations, if such is to be found. Whilst tariffs show a consistent tendency to fall, traffics have, the Directors are pleased to report, shown a gratifying rise during the year. There is only one way to deal with increasing traffics, and that is the attainment and maintenance of perfect methods of transmission with the highest class of instruments and apparatus of all kinds obtainable. Well, gentlemen, we can say that we have no fear of reproach on the above grounds. Our friend, the Managing Director, is continually at work on the development and improvement of the system, but there is a limit even to his ingenuity, and we are faced with the necessity of permanently increasing our carrying capacity all through our system, with attendant expense. The Directors have set aside out of profits for the year a sum of £15,000 towards the cost of the additional land wire found necessary, and hope to provide a considerable further amount for the same purpose out of profits for the coming year. The cost of additional cable accommodation is, of course, a much heavier one, and the question is still engaging the attention of the Directors. I have often congratulated you on the financial position of this Company. Its large liquid assets enable the Directors to meet at a moment's notice commitments such as these, which might, ordinarily speaking, be almost heavy enough to necessitate the raising of fresh capital.

The Company's daily direct working between London and Karachi is of the greatest assistance in dealing rapidly and accurately with the traffic, and the Directors are constantly endeavouring to better the Company's own reputation in this respect. Yet we cannot keep pace with the demands of our customers, who expect their code words to be carried 7,000 miles to India without the failure of a single letter, the failure of one letter only having, apparently, the most disastrous results upon the sense of their telegram. This carries us back to the vexed

Digitized by Google

question of pronounceable, or rather, unpronounceable, combinations. No improvement is visible in the construction of these codes—in fact merchants, in their endeavour to condense even a complete order into the limits of one code word, are forced into combinations of letters which practically make correct transmission a matter of the utmost difficulty. In this manipulation we think that he is defeating his own object by the abuse of the pronounceable combination system. It is sincerely to be hoped that the International committee provided for the censorship of codes submitted to it may be the means of standardising pronounceable-combination codes on a more reasonable basis. Turning to the accounts the revenue from message receipts and other sources, as shown in the revenue account, shows a satisfactory increase of £12,766. 13s. 1d. The combined commercial and maintenance expenses show an increase of £2,562. 7s. 8d. due to an item of expenditure on maintenance account of a non-recurring nature. The balance-sheet shows no variation from last year calling for remark. The Directors propose the usual final dividend, which absorbs £14,875, and bonus of 20s. per share, which accounts for a further £17,000, and have again decided to recommend a special distribution out of interest upon certain investments and advance accounts of 15s. per share, free of tax in each case. There remains a sufficient surplus to enable the Directors to propose the allocation of £15,000 towards the cost of increasing the carrying capacity of the system (which will, of course, ultimately amount to a considerably larger sum) and of a further sum of £5,000 to the trustees of the retirement trust fund, carrying forward £7,978. 1s. 11d. to the credit of 1910. This, gentlemen, finishes my review of the Company's operations for the year 1909. With regard to our prospects for 1910, traffics have, for the months up to date, been quite unprecedented, so that, provided our business is not dislocated by Channel cable interruptions, or any of those bolts from the blue to which undertakings such as ours are at all times exposed, we may hope for a prosperous outcome of the year 1910. I now move the adoption of the report and accounts, and the declaration of the dividends and bonus set out therein.

Mr. CHARLES HOLLAND seconded the motion, which was carried unanimously.

The re-election of the retiring Directors (Mr. C. Holland and Mr. George Plate) and the retiring auditors (Messrs. C. F. Kemp, Sons, & Co.) followed, and a vote of thanks to the Chairman, the Directors, and the officials for their strenuous and successful efforts on behalf of the Company brought the proceedings to a close.

Cuba Submarine Telegraph Co. (Ltd.)

The seventy-seventh ordinary general meeting was held on Wednesday, Mr. GEO. KEITH in the Chair.

The SECRETARY (Mr. James Scott) read the notice convening the meeting and the auditors' report.

The CHAIRMAN: Gentleman, the period under review from July to December is usually the lean or dull half of the year. You will be pleased to see that the half-year's traffics compare very favourably, as a whole, with those for the same period of 1908. The improvement shown may be attributed partly to the more active state of business following a good harvest, and partly to an increase in the Press and other traffic, in consequence of the exceptional storms and floods which took place in Cuba and the West Indies during the half-year. Bad weather in Cuba interferes with the working of the land lines, especially in the Western portion of the island, and leads to a larger use of our cables along the South Coast for local business. There was the hurricane in November, and as a consequence cable communication with the West Indies was entirely cut off for over a week. Fortunately our cables, as also the cables from Santiago to Jamaica and Hayti, were unaffected, and the through traffic lost during that time was more than made up by the large increase after the restoration of that communication, which accounts for the exceptionally good traffic for November, while the early commencement of the sugar harvest contributed to the increase in December. Now, turning to the revenue account, the traffic receipts of the half-year show an increase of £1,367 as compared with those of the corresponding period of 1908. Interest comes out £153 more, owing to our having made a further investment, and to the better rate received from our deposit at the bank. Taking transfer fees into account the gross revenue amounts to £16,376, or £1,518 more than it was in 1908. On the debit side the London expenses are much about the same, but expenses at stations are £287 more. Maintenance of land lines increased by £324, due principally to repairs having to be made to the Havana Batabano landline, and to the Cienfuegos Bay cables and cable huts. Income tax is also £119 more owing to the higher rate now current, and to an increase in the average of the three years upon which our return is based. Altogether the total expenses amount to £6,415, or £389 more than they were in 1908. The result of the half-year's business is a balance of profit of £9,961, which, after putting £2,000 to the reserve fund and providing the dividend of £3,000 for the preference shares, enables the Directors to recommend the payment of the usual dividend at the rate of 6 per cent. per annum on the ordinary shares free of income tax, and to increase the balance carried forward by £161 to £7,220. I think we may consider the result as very satisfactory. We have practically carried the interest earned by our investments to the reserve fund, increasing it to £116,000. So long as we are able to do this for the dull and lean half of the year, and a little better out of earnings of the business for the busy half, we are pursuing a safe and sound policy, but at the same time we have to keep in mind that we have over 1,200 miles of cable to maintain, and it is necessary to go on adding to the reserve fund so as to be able to meet the renewals and repairs which may have, in the future, from time to time, to be made, without unduly reducing its amount and taking away its recuperative power. As regards the present year, business generally is good and active. Cuba continues very prosperous under its own government; new industries are springing up in the island which all help to increase its prosperity; and works are going on in connection with railway extension, building of wharves and warehouses and making new roads and bridges, all of which when completed, will facilitate the transport and shipment of the produce of the island.

I now move the adoption of the report and accounts.

Mr. CHARLES W. PARISH seconded the motion.

Mr. GEORGE LYDDON referred to the statements made in the public journals regarding Marconi's wireless telegraphy, and said he would like to know, in the face of the suggestion that soon submarine telegraph cables will not be required, and that wireless telegraphy will be the only thing known throughout the world, whether they were to be in a state of collapse or to go on in the prosperous course they had hitherto done and were still pursuing.

The CHAIRMAN: Well, gentlemen, I know that a great deal of communication is being made on the sea by wireless telegraphy, but as regards communicating overland, as far as I know I do not think it has been very successful. In my own opinion, the drawback of wireless telegraphy is the want of the wire—(laughter)—and I do not think, so far as we are concerned, that we need fail to sleep soundly over the matter itself. Although wireless telegraphy is getting more and more important, I do not think we have much to fear. I understand they can communicate a longer distance from the land to the ship than from the ship to the land, and that the distance that can be communicated over from the ship is very limited—much more so than communication in the other direction. For instance, just now they say they are communicating across the Atlantic. Well, if they use tremendous power no doubt they can do so; but whether it will be successful or not remains to be seen.

A resolution approving the preference and ordinary dividends was then carried unanimously, and a cordial vote of thanks to the Chairman terminated the proceedings.

AUCKLAND ELECTRIC TRAMWAYS CO. (LTD.)—The directors' report for 1909 states that the total revenue was £182,594. 8s. 3d., and the traffic receipts (£180,386. 15s. 11d.) show an increase of £16,538. 14s. 2d. over 1908. Deducting expenses, including £16,454. 13s. 8d. for interest, the rental and percentage of profits payable to Auckland Council (£3,992. 10s. 11d.), and setting aside £15,000 (compared with £12,500 last year) to depreciation, the surplus was £35,124. 1s. 1d., or, with £3,920. 7s. 8d. forward, £39,044. 8s. 9d. The directors recommend that £11,500 be placed to reserve, that £3,000 be appropriated to preference dividend, and that a dividend be paid on the ordinary shares at the rate of 6 per cent. (making 6 per cent. for the year) (£21,000), leaving £3,544. 8s. 9d. to be carried forward. Capital expenditure during the year was £56,601. 7s. 4d., the largest portion being in connection with an extension of the power house plant and distributing system. An extension of 0·68 mile in the Grey Lynn district, which is now approaching completion, was commenced, and five additional cars were purchased. At the request of Auckland Council the company have agreed to construct an extension of about ¼ mile of tramway. An extension of 0·775 in another district has also been agreed to. Further suggested extensions of the system are under consideration. Eight further cars have been ordered and are under construction, bringing the total up to 100.

BABCOCK & WILCOX (LTD.)—At the meeting on Friday the chairman (Mr. John Dewrance) said the company had earned a record profit. It was proposed to pay for the six months ended Dec. 31 last, besides the accrued dividend on the preference shares, a dividend of 8 per cent. and a bonus also of 8 per cent. on the ordinary shares. In addition, the board recommended that £100,000 be placed to reserve and £25,000 to dividend equalisation fund. It was felt that the time had come to create a staff pension fund, and £10,000 had been set aside for that purpose. The amount carried forward was £63,082. The factory had been largely increased, and the plant and organisation considerably improved, and they were still further extending the works. With regard to the pension fund, it was intended to limit its benefits to the heads of departments and what was called the staff. The question of providing for the workmen must be left to the Government. It was not easy to make any provision for workmen, because they changed their employment so frequently, and their trade unions and other arrangements interposed a great number of difficulties.

DEVONPORT AND DISTRICT TRAMWAYS CO—At the meeting last week the chairman (Mr. W. G. Bond) dealt at length with the dispute between the company and Devonport Corporation. The past year had been an abnormal one (especially on the expenses side), and during 11 months the Corporation extensions were not operated. In 1908 the traffic receipts were £24,402, and in 1909 they were £19,255. Seeing that the total annual sum paid to the Corporation under the lease was only £3,900, it might be said that the company had been trying to bluff the Corporation in arguing, as it had done, that the extensions constituted such a drain upon their resources that the company was entitled either to some measure of relief or to purchase upon terms not appreciably worse than those of the 43rd section of the Tramways Act, 1870. He contended that the figures bore out the company's contention and that the company was justified in promoting the "Relief" Bill which was recently rejected by a Select Committee of the House of Commons. After sketching the proceedings before the Committee, Mr. Bond stated that the company only wanted fair play. That they had never had. Every concession and suggestion had come from the company. They

would gladly come to terms with the Corporation upon any reasonable basis, but it had declined, and would continue to decline, to hand over its undertaking to the Corpoartion for a mere song.

GENERAL ELECTRIC CO. (U.S.A.)—The report for 1909 states that the gross earnings were $54,102,000, increase $6,945,000; net earnings $9,599,000, increase $2,556,000; balance, $6,494,000, increase of $1,691,000; and surplus to profit and loss account, $1,279,000, increase $1,691,000 over 1908.

LONDON UNITED TRAMWAYS (LTD.)—At the meeting last week, Mr. C. J. Cater Scott said that up to 1906 there had been a reasonable expansion in receipts, but since 1906 that expansion had diminished, until last year they were face to face with a very serious falling off. In 1906 they had 45 miles of route open, and their traffics were £325,000; in 1907 they had 52¼ miles open, and their receipts were £342,000; in 1908, with 55¼ miles open they had £346,000 from traffics, or nearly £4,000 more, and in 1909, with the same route mileage, their traffics were down to £317,000. Bad weather and competition were responsible for this drop in receipts. Competition was by far the most serious cause with which they had to deal. During the last four years there had been an absolute revolution in the conditions under which London passenger traffic had been carried on. During that period they had had the District and Metropolitan Railways electrified. They also had the three big tubes. There was one other factor, and it was the most important of all so far as they were concerned, and that was the motor 'bus. There were now just over 1,700 motor 'buses on the streets of London, and they were undoubtedly the most serious competition with which they had to deal. In dealing with that competition they were at a very serious disadvantage. A motor 'bus could run where it chose. During the week it could work any route in London itself and on Sunday it could be sent to those districts where their tramways were, and where, hitherto, they had had comparatively little competition. Unfortunately, with the lack of expansion of business they had concurrently had a considerable increase in maintenance expenses, and for some time to come they must certainly look for very considerable charges against revenue for maintenance. Many of their lines had been carrying a heavy traffic for a good many years past, and, naturally, they had begun to show signs of wear and tear. In 1909 they carried 55,750,807 passengers, against 59,255,919 in 1908. On traction expenses they had a saving of about £3,566, due to some reduction in car-mileage, and also chiefly to a considerable reduction in coal. In traffic expenses there was an increase of £1,099, entirely accounted for by compensation and legal expenses, which were up £1,890. There were also increases in salaries and management expenses. There was an increase of £2,252 on rolling stock and power plant, £1,572 on overhead lines and cables and £4,631 on maintenance. They had a total increase in expenditure of £6,334, and with the diminution in traffics they were £37,499 worse off than in 1908. London County Council had served them with notice to purchase the Hammersmith line. In regard to the retirement of Sir Clifton Robinson, that gentleman had been associated with the company for a great many years as managing director, and had devoted himself almost entirely to its work. But Sir Clifton Robinson had this year completed 50 years' service in connection with tramways in one part of the world or another, and thought the time had come when he was entitled to some rest. The London United Tramways was very closely associated, through the Underground Electric Railways Co. of London, with the Metropolitan District, the Piccadilly, Hampstead and Bakerloo Tubes, and it had been thought that if they could do something more with that closer association, if the London United Tramways could be brought under the same general management as those other companies, it might be of great benefit to the London United Co. Sir Clifton Robinson realised the position, and helped to carry it out; so that his retirement came as a friendly act. In his place they had elected Mr. Stanley (the general manager of the District Railway and of the three tubes mentioned) to be their managing director. Mr. Chapman, one of their directors, had left the country, and had resigned his seat.

ORIENTAL TELEPHONE & ELECTRIC CO. (LTD.)—The chairman (Mr. B. St. John Ackers) stated at the meeting on Wednesday that satisfactory progress had been made during the past year and the prospects were encouraging. There was also a steady development in the business of the subsidiary companies. The negotiations between the Calcutta Co. and the Indian Government for taking over the telephone system were occupying the board's attention. In Egypt the progress did not equal that made during the years immediately preceding the recent crisis. The China & Japan Co. was able to report satisfactory developments at Hongkong and the progress made by their branch in Kowloon was equally marked.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON (LTD.)—At the meeting last week the chairman (Sir Edgar Speyer) said that the net revenue for the half-year not only showed a substantial improvement, but was sufficient to pay the full half-year's interest on the 4½ per cent. bonds. The good results which had been obtained were chiefly due to savings in coal consumption and other reductions in cost of working the Lot's-road power station, to providing the quickest and most efficient service that it was in their power to give, and to spreading, through a well-conceived plan of advertisement, the information regarding the many exceptional travelling facilities which their system offered. The affiliated companies carried 217,730,081 passengers in 1909, of which the three tubes carried 95,126,973, the District Railway 66,852,301 and the tramways 55,750,807. That would enable them to realise what an important contribution to the traffic problem of London they were making—in fact, to imagine London to-day without the tubes was hardly possible, although it was less than three years ago that they were completed. The scheme to amalgamate the three non-competitive tube companies was not an ordinary case of railway amalgamation, but was a measure of financial common-sense.

Their late chief engineer's (Mr. J. R. Chapman) agreement having terminated, and his task having been accomplished, he had returned to America. The company owed to Mr. Chapman's engineering skill and untiring energy, as well as to his unfailing loyalty, a deep debt of gratitude. The Chelsea power station was entirely due to his initiative, courage and ability.

The District Railway continued to make encouraging progress. The appointment of their general manager (Mr. A. H. Stanley) as managing director of the London United Tramways would mean unification of management and the spreading of their organisation over that system. They confidently expected that by that means better results would be obtained.

TYNEMOUTH & DISTRICT ELECTRIC TRACTION CO. (LTD.)—Including £315 brought forward, the profits for 1909 were £4,566. A dividend of 3½ per cent. per annum is recommended, £148 being carried forward.

URBAN ELECTRIC SUPPLY CO. (LTD.)—The gross profits for 1909 amounted to £44,872, and over £43,000 is available. Deducting £12,263 for interest and £1,971 for depreciation, there remains £23,877, which falls short by £3,622 of the amount required to meet the 5 per cent. guaranteed dividends. This deficit has been provided by Edmundsons' Electricity Corpn. under their contract.

WEMYSS & DISTRICT TRAMWAYS CO.—For the year ended Dec 31 last the traffic receipts amounted to £13,653. The total income was £13,909, and the balance at credit of profit and loss account was £2,599. The directors recommend a dividend of 6 per cent. on the ordinary shares. £302 is carried forward.

CITY NOTES.

MEMORANDA (April 28).—**Bank rate 4 per cent.** (since March 17, 1910). **Price of silver,** 24⅛d. per oz. Consols 81--81¼ for money and for account. Consols Pay Day, May 5; Stock and Shares Continuation Days, May 10 and 29; Ticket Days, May 11 and 26; Pay Days, May 12 and 27; Mining Shares Carry Over Day, May 9.

PRICES OF METALS (London).—*Copper*, cash, 5⅝; three months, 57¼. *Lead*, English, 12⅞—13⅛; foreign, cash, 12⅞—12⅞; three months, 12¼. *Spelter*, 21⅞—22⅛. *Tin*, English, 149—151; foreign cash, 150¾; three months, 151¾. *Iron*, Cleveland, cash, £0,3, and three months, 51/3.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The directors, after writing off £17,000 for depreciation and renewals, have declared a dividend at the rate of 9¼ per cent. (4s. 9d. per share) for the half-year to Dec. 31 (making 8 per cent. for the year).

CITY OF BUENOS AYRES TRAMWAYS CO.—A dividend of 1s. 3d. per share (less tax) is announced for the three months ended March 31.

COLOMBO ELECTRIC TRAMWAYS & LIGHTING CO. (LTD.)—The directors recommend a dividend of 6 per cent. (12s. per share), tax free, for 1909, after allocating £7,300 to reserve and renewals and writing £5,300 off track renewal account, &c, and carrying £2,201 forward.

EASTERN TELEGRAPH CO. (LTD.)—This company announce that, subject to final audit, the accounts for the year ended Dec. 31, 1909, show that after making a contribution to general reserve, payment of interest on the 4 per cent. mortgage debenture stock, dividend on the 3½ per cent. preference stock and three interim dividends of £1. 5s. per cent. each on the ordinary stock to Sept. 30 last, there is a balance available out of which the directors recommend payment of a final dividend of £1. 5s. per cent. and a bonus of £2 per cent., both tax free, and payable on May 11, making with previous payments on account a total distribution of 7 per cent. on the ordinary stock for the year 1909. The transfer books of the ordinary stock will be closed from May 4 to 11 inclusive.

EASTERN EXTENSION AUSTRALASIA & CHINA TELEGRAPH CO. (LTD). Subject to confirmation by the shareholders, the directors have declared a dividend for the quarter ended Dec. 31 last of 2s. 6d. per share, together with a bonus of 4s. per share (or 2 per cent.), making a total distribution of 7 per cent. for 1909. The dividend and bonus will be paid on 11th prox. The share register will be closed from 3rd to 10th prox. inclusive.

RIVER PLATE ELECTRICITY CO. (LTD.)—The directors, after placing £10,000 to reserve, have declared a dividend of 9 per cent. (less tax) on the ordinary shares for the year to Dec. 31, carrying forward £5,141.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have granted quotations to £170,000 £1 (7s. 6d. paid) 6 per cent. cumulative preference shares of *La Plata Electric Tramways Co. (Ltd.)* and a further issue of £200,000 £5 per cent. cumulative perpetual preference, £200,000 preferred ordinary and £100,000 deferred ordinary stock of the *British Columbia Electric Railway Co. (Ltd.)*. The committee have been asked to grant quotations to 70,000 £5 fully-paid ordinary and 14,000 £5 fully-paid 6 per cent. cumulative preference shares and £700,000 5 per cent. first debenture stock (renewed special application) of the *Para Electric Railways & Lighting Co. (Ltd.)*

WEST INDIA & PANAMA TELEGRAPH CO. (LTD.)—The directors recommend payment of the following dividends: 6s. per share on the first preference shares (for six months to Dec. 31) and 9s. per share on the second preference shares (on account of dividends accrued to Dec. 31, 1909).

Allen Electrically-driven Pumping Plants.

THE very varied uses to which pumps of the electrically-driven centrifugal type can be applied are well exemplified in the following instances, each of which is in its turn only typical of the large number of

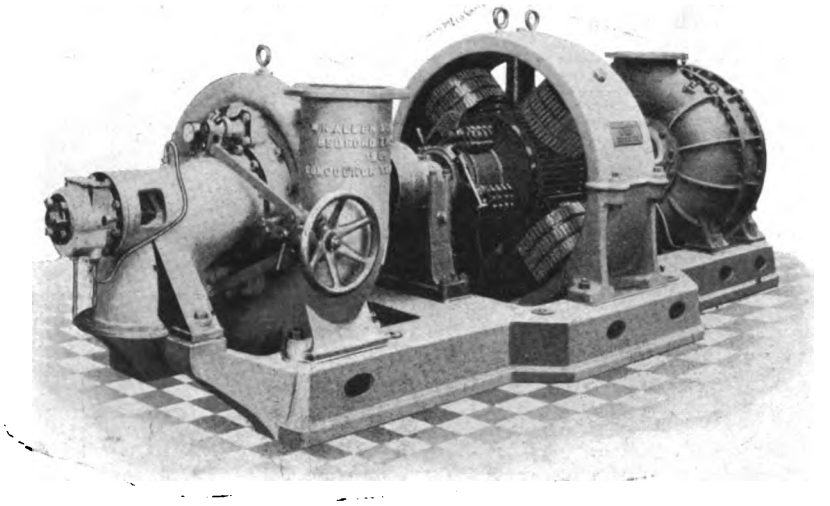

Fig. 1.—Pump for Newcastle Manor Sub-station.

installations which have been equipped by Messrs. W. H. Allen, Son & Co., of Bedford, the actual machinery in each case having been constructed by this firm at their works at Bedford. As is well known, their "Conqueror" centrifugal pumps for moderate lifts have held for many years a high reputation, and in the more recent development of turbine pumps for high lifts Messrs. Allen have devoted the results of a long experience of hydraulic machinery to the perfection of a type of high-lift pump which is, it is claimed second to none in its performance, and which, in the class of materials and workmanship employed, has few equals.

Circulating Pumps.—As an efficient and in every way suitable appliance for supplying the cooling water for condensing plant the centrifugal pump has a long-established reputation, and as the arrangements of all the various systems are now matters of common knowledge, it is unnecessary here to devote any space to them. An interesting variation, however, upon the usual plan which is applicable when the condensing plant is situated at a considerable height above the water supply level, the water returning to the original level has recently been carried out by this firm in a few instances. In such a case it is obvious that in the event of the total fall from the condenser being more than about 30 ft. the excess of potential energy of the water above this height would be entirely lost, and it is with the object of avoiding this loss that the present plant has been designed. The hydraulic plant consists of a two-stage turbine pump constructed throughout of special bronze, and coupled direct to a continuous-current motor and a water turbine of the Francis inward-flow type, also constructed throughout of bronze. This set was built for the Newcastle Corporation tramways, and is now at work in their Manor power station. The pump has to deliver 2,500 gallons per minute against a head of 120 ft. at 650 revs. per min., the plant being situated near the water supply level. The turbine receives the return water from the condenser under a head of about 100 ft., and is fitted with adjustable guide-blades to enable it to deal efficiently with variations in the quantity of water. The motor has a capacity of about 58 kw. at 500-550 volts, but on trial at the makers' works, when the complete plant was fully tested, the maximum electrical input was found to be only about 52 kw., the effi-

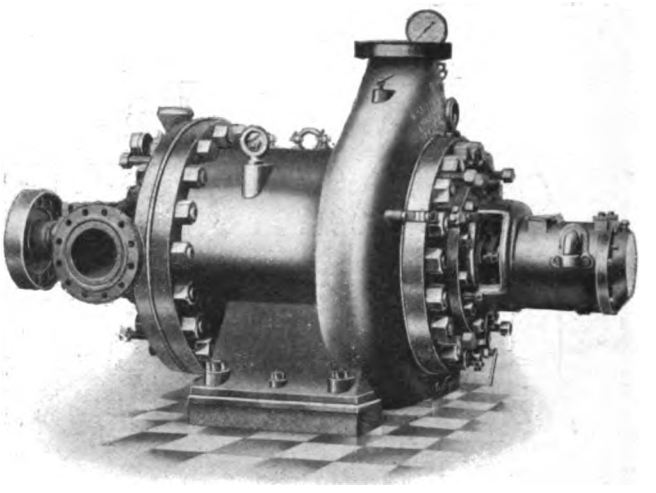

Fig. 2.—Allen Mine Pump.

Digitized by Google

ciencies of turbine and pump being 79 per cent. and 75 per cent. respectively. The test results proved in the aggregate to be 11 per cent. better than the guarantee.

Dock Pumps.—The great advance in recent years in the application of electrical power in factories and dockyards now renders it possible for the heaviest work to be carried out by electrical power. In many cases a considerable saving in capital can be thereby effected. The problem of dry-dock pumping affords an excellent example of the application of electrical machinery in a dockyard where abundant electrical power is available. It is obvious that a large and

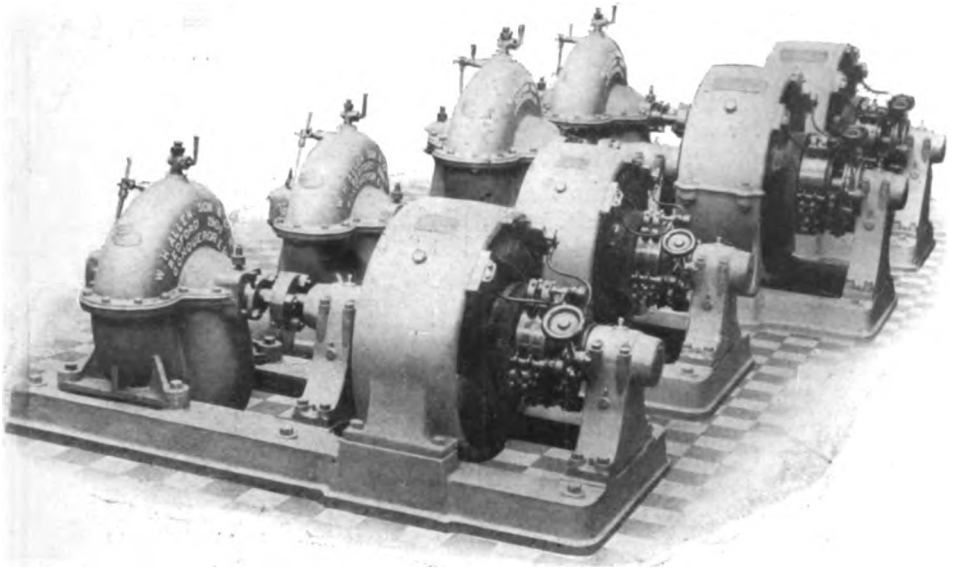

Fig. 3.—Sewage Pumps for Canterbury.

costly steam plant with all its attendant expenses of upkeep, &c., and which is only called upon to operate at very irregular intervals affords anything but an economical solution of the problem. The present instance of a powerful plant, which has been constructed and equipped by Messrs. Allen for a dockyard in the Far East, is a good example of this particular development. It consists chiefly of three of their twin-parallel centrifugal pumps, having suction and discharge branches 42 in. in diameter, and each coupled direct to a three-phase motor of 400 B.H.P. Each set is designed to discharge 24,000 tons of water per hour against a mean head of 22 ft. when running at 352-392 revs. per min. The motors are designed to develop 400 B.H.P. at the above speed when supplied with current at 60 periods and at 1,050 volts. These motors are also capable of developing an overload of 20 per cent. for one hour. In addition to these are two vertical-spindle electrically-driven drainage pumps, each having 12 in. branches and capable of delivering 2,500 gallons per minute against a 60 ft. head at 880 revs. per min. and absorbing 120 B.H.P. Priming of the main pumps is effected by a two-throw Allen-Edwards air pump, having barrels 10 in. in diameter with a stroke of 7 in. This is gear-driven by a 6 B.H.P. motor running at 1,150 revs. per min., the air-pump making 230 revs. per min. The motor works at 220 volts, receiving its current from a small oil-cooled transformer. The three main sluice-valves on the discharge branches of the main pumps are opened and closed by hydraulic pressure, which is supplied from an electrically-driven three-throw ram pump. Liquid starters are provided for the three main pumps, the drainage pumps and hydraulic pump motor. The whole plant is controlled from a switchboard having a raised platform in front and accessible by a stairway from the pump room floor.

Mining Pumps.—The easy adaptability of the turbine type of centrifugal pump to high lifts without any serious loss of efficiency, combined with its mechanical simplicity and compactness when driven direct by electrical power, as well as its great smoothness in running, renders this type

of pump highly suitable for the work of mine pumping. One of the best examples of a thoroughly up-to-date plant of this kind is to be found in the case of two electrically-driven pumps which have recently been constructed by Messrs. Allen for a gold mining company abroad. Each pump has an output of 525 gallons per minute against a head of 1,450 ft. when running at a speed of 1,600 revs. per min. These pumps each have seven stages, and the considerable length of the pump, which is the consequence of the large number of stages combined with high speed of rotation, has necessitated special care being taken in the design of the rotary parts to ensure good balance and freedom from vibration. The casings of the pumps and the end covers, which are of cast iron, are necessarily of very substantial design to withstand the great pressure due to the head of water. The spindles are of nickel steel and are fitted with bronze liners where they pass through the glands. The discs and guide blades are also all constructed of special bronze, and the

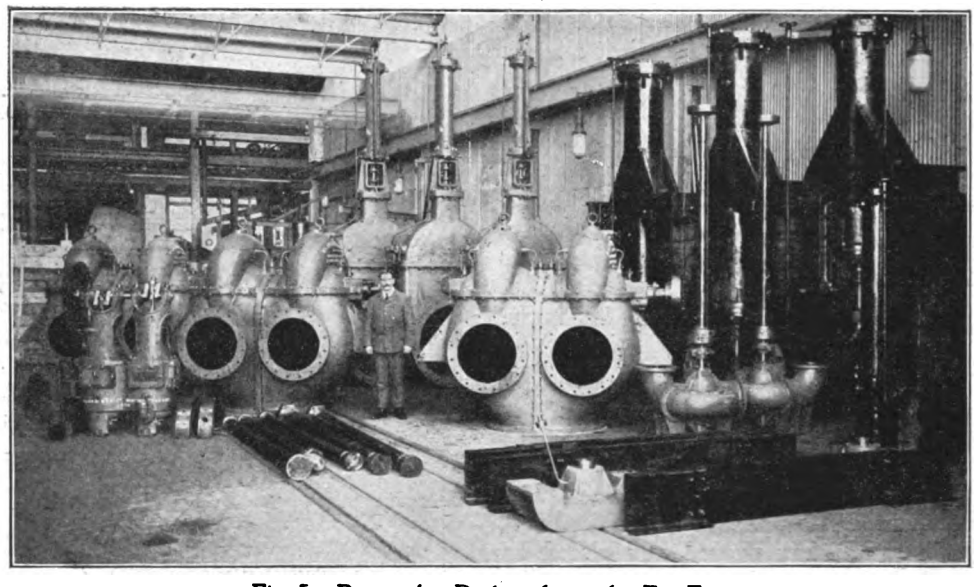

Fig. 5.—Pumps for Dockyard in the Far East.

Digitized by Google

resultant end pressures on all the discs are automatically balanced by hydraulic pressure by means of a patented device. The motors are of the continuous-current high-speed type and are coupled direct through flexible couplings to the pump spindles. As the whole plant had to be lowered down a shaft of very limited section, the base-plates were each constructed in three pieces and bolted together on the site underground.

Boiler-feed Pumps.—As in the previous example, the suitability of the turbine pump of high efficiency for large heads has brought it into the field of boiler-feed pumping. In installations where a total quantity of 50 gallons per minute and upwards is required it is eminently suitable. Reciprocating pumps, if of the direct-driven type, consume a large amount of steam for the work done, the steam being often conveyed through a great length of small and inefficiently lagged piping, and reaching the pump more than half in the form of water. If gear-driven, plunger pumps are usually noisy in operation, expensive to instal and complicated, and special arrangements are necessary for a wide variation of speed in order to vary the quantity sufficiently, or a complicated gear for varying the stroke of the plungers becomes necessary. The turbine centrifugal pump, on the other hand, is silent in working, and delivers a continuous stream of water without any pulsations. Where floor space is limited it can be arranged with its spindle vertical, and it can run continuously with very little attention with a good efficiency over a wide range of loads. The pump illustrated is of the six-stage vertical-spindle type, and is designed to deliver 100 gallons of water per minute against a pressure of 210 lb. per square inch when running at 2,200 revs. per min. The usual automatic balancing device is employed, and the top bearing of the pump is also designed as a multi-collar thrust bearing to take the weight of the revolving parts when at rest and at very low speeds, and is fitted with automatic oil circulation. The electrical motor is situated vertically above the pump, and is coupled to it through a flexible coupling which cannot transmit any end thrusts. The weight of the electrical motor is carried on a special ball thrust bearing above the motor in a very accessible position, the remaining bearings being also of the ball pattern.

Vertical Spindle Pumps for the Dublin Graving Dock.

SOME interesting electrically-driven pumping sets have recently been built and installed by Messrs. Drysdale & Co., of Yoker, Glasgow, for the Dublin Port and Dock Board. The complete pumping installation consists of two main vertical spindle pumps having suction and delivery branches 30 in. in diameter, two vertical spindle drainage pumps having suction and delivery branches 6 in. in diameter, and one motor gear-driven vacuum pump for charging purposes. The centrifugal pumps are all of the side-cover type, and are supported on stools resting upon the stone floor of the wells. Each of the two wells contains one main pump and one drainage pump with the necessary valves, all the latter being worked from the engine room by means of spindles carried up through the floor. The bottom of each well is 28 ft. below the floor of the engine house, and thus only one 16 ft. length of intermediate shafting requires to be employed for coupling the pump to the motor. An illustration is given of one of the main pumps from which the main points of the construction can easily be gathered. The weight of the motor armature and vertical shaft is carried by the ball bearing on the top end of the motor. The vertical shaft is joined to the pump shaft by means of flexible coupling, while, to prevent any possibility of downward pressure occurring from some unforeseen cause and proving injurious to the impeller, a ball bearing is situated just above the pump. This bearing also forms one of the pump journals. The drainage pumps were arranged on the same system and have proved satisfactory in every way. Each main pump has a separate discharge pipe, but both of these pipes discharge into one main culvert which leads to the harbour basin outside the dock. The main pumps are self-charging right down to the point when the bottom of the dock is laid bare, that is, so long as the water in the sump is deep enough to cover the mouth of the suction pipe properly. As a safeguard, however, the motor gear-driven vacuum pump referred to above is installed for cases of emergency. This pump is of the single-throw plunger type and is driven through raw-hide gearing by a motor.

The electrical part of the installation was supplied by the Lancashire Dynamo & Motor Co. to Messrs. Drysdale's order. The motors for each main pump are of 300 B.H.P. capacity rating, and are of the shunt-wound semi-enclosed interpolar vertical spindle type, and are designed for working on voltages between 480 and 500, the range of speed being from 210 to 280 revs. per min. The motors for the small drainage pumps are each rated at 13 B.H.P. and are of the shunt-wound semi-enclosed vertical spindle type, having a speed range from 600 to 800 revs. per min. As before mentioned, the weight of the armature is carried by ball bearing on the top of the motor.

Each pump was guaranteed to pump out the dock in two hours, and the actual time taken on the trial run was 1 hour 35 minutes, or 25 minutes inside the guaranteed time. The pumps are of special design, such that a very large quantity of water could be discharged, the efficiency at the same time being kept at a very high point. The whole installation has been completely satisfactory in every way, and the combined efficiency of these pumping sets has been maintained at an exceptionally high standard, the plant being designed to meet the requirements of Mr. Purser Griffiths, M.Inst.C.E., the engineer of the Port and Dock Board of Dublin, under whose superintendence and to whose order the work has been carried out.

B.E.P. Centrifugal Pumps.

AMONG the firms who have recently taken up the manufacture of centrifugal pumps, the British Electric Plant Co., of Alloa, N.B., have quickly made for themselves a prominent place, mainly due to the special system of balancing the impellers which they have developed. The device in its application is protected by a patent, and its principal claim for recognition is its simplicity, for it forms a radical departure from existing types of centrifugal and turbine pumps, permitting the entire absence of special provisions for neutralising end-thrust.

A large number of B.E.P. pumps have already been installed, and in the majority of these cases they are driven by the same firm's alternating-current or special high-speed direct-current machines. Within 6 miles of the works there are as many pumps at work, at three of the pits belonging to the Alloa Coal Co. and at each of these pits the generating plant was also supplied by the B.E.P. Co.; Fig. 1 showing one of the 475 k.v.a. 50-cycle 650-volt alternators there in use. The speed selected for the pumps was 1,450 revs. per min., squirrel-cage motors being used to drive them. At two of the pits two pumping sets in series are being used to unwater a dook, the arrangement being that one set is fixed in a permanent position, the other following the water as it recedes. As a consequence, the parts requiring to be handled when the portable set is taking up a new position are considerably lighter than they would be if the entire lift were done with one set. In one case the stationary set (Fig. 3) is capable of delivering 600 gallons per minute against a total head of 405 ft. For supplying the water to this pump, a semi-portable equipment of 500 gallons capacity is used, and is capable of dealing with a total head of 350 ft., the design being similar to that of the stationary set.

At the second of the above-mentioned pits, the quantity of water dealt with is 100 gallons per minute, the total head being 340 ft. Direct-current variable-speed B.E.P. motors, supplied from 440-volt direct-current generating plant at the surface, drive the pumps, and the sets are identical in every respect. As the pit is classed as being "fiery," the motors are of the totally-enclosed type, similar to that shown in Fig. 4, and are fitted with radiating ribs to assist cooling. Their capacity is 10 B.H.P. when running between the speeds of 1,350 and 1,450 revs. per min.

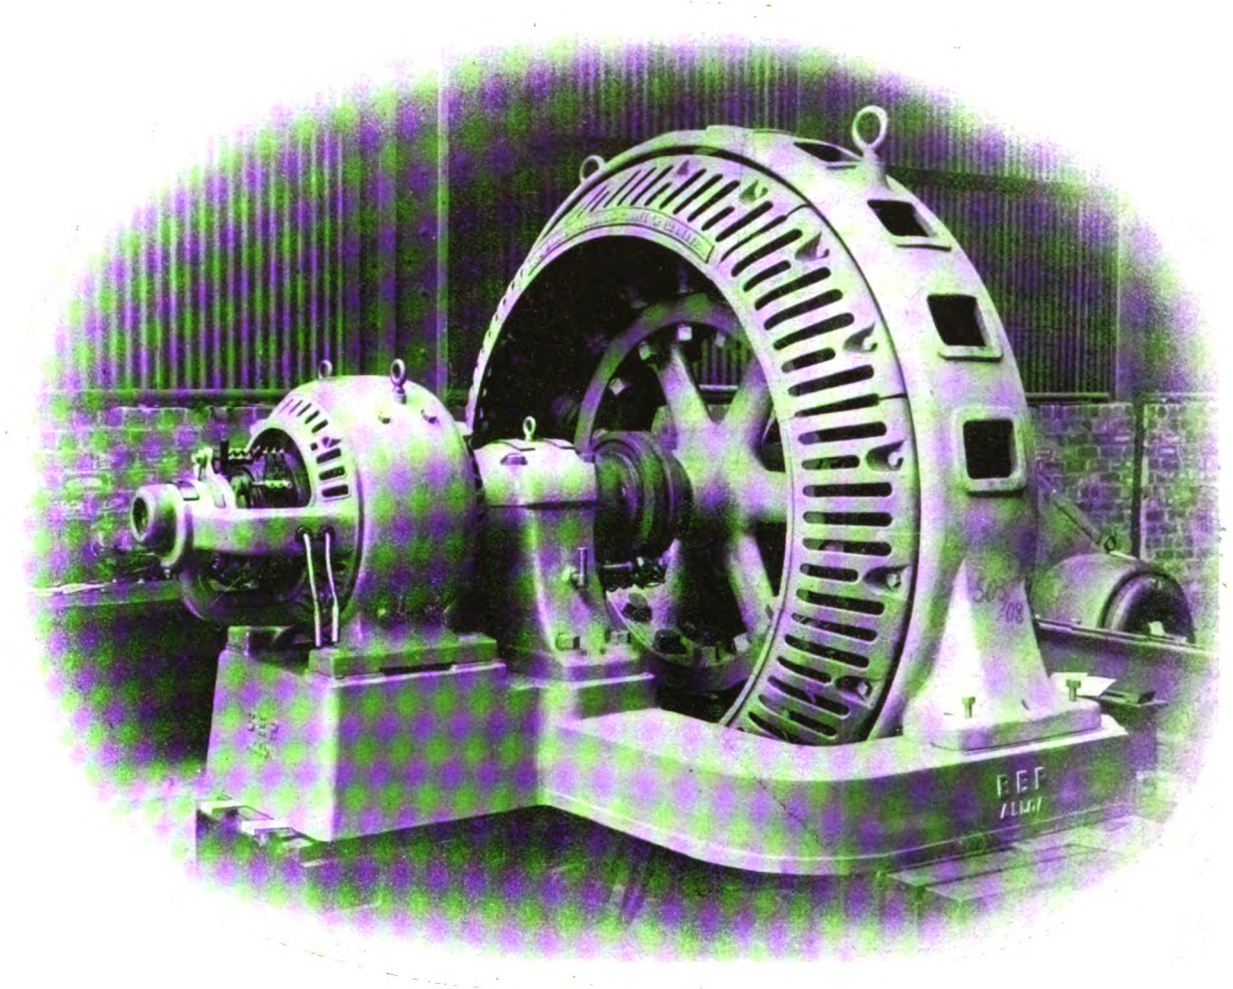

Fig. 1.—B.E.P. 475 k.v.a. Alternator.

Another interesting set recently supplied by the B.E.P. Co. is also in use for dook working, the pump again being driven by a variable-speed direct-current 45 B.H.P. motor fitted with interpoles. The pump is designed to deal with a constant quantity of 400 gallons per minute against a total head increasing from zero to a maximum of 200 ft. The units are mounted together on a channel and angle-iron bogie for operation on a gradient of 1 in 6, the entire control and starting apparatus being carried on a frame at the motor end of the set. A special point in connection with dook pumping by means of such a set is a device which the B.E.P. Co. employ when the work to be done consists of

Digitized by Google

unwatering at a constant rate against a varying head. When the limits of the head are not too wide, the conditions can be satisfactorily met by the use of variable-speed motors when a d.c. supply is available, the speed being adjusted by means of a shunt regulator to enable the pump to discharge the desired quantity without having to throttle. When, however, the variation in the head entails an exceptionally heavy direct-current motor to give the full output at the lowest speed, or when the supply is alternating current, resort has to be made to the device already referred to, which consists in leaving out certain of the impellers and fitting so-called "dummy" chambers. By so doing the

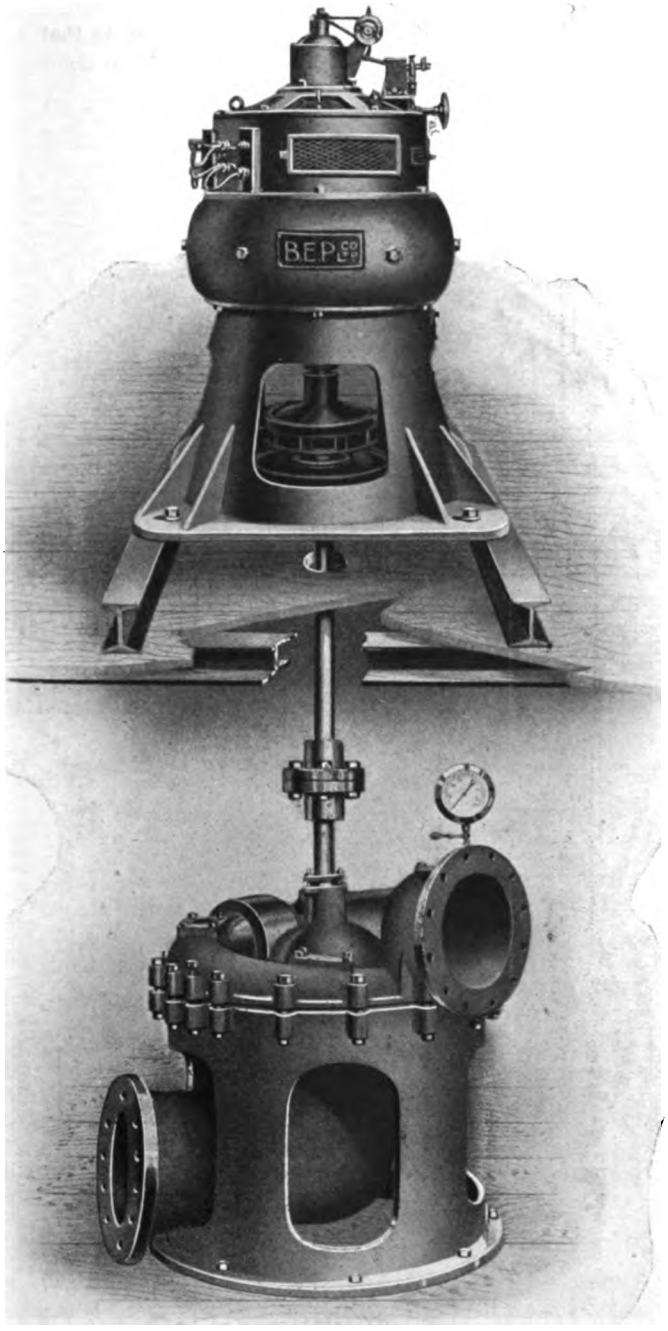

Fig. 2.—Vertical Pumping Set for use on Tideway.

total head given by the pump is reduced in the same proportion as the number of impellers removed to the original number, and as this also reduces in the same proportion the power required at normal quantity there is a considerable saving in the total expenditure of energy which would have been entailed if the pump were arranged to give a constant head, and in consequence had to be controlled by a valve to limit the discharge. Further, by this device the discharge may be considerably increased without overloading the motor, and the unwatering, when such is the operation, may

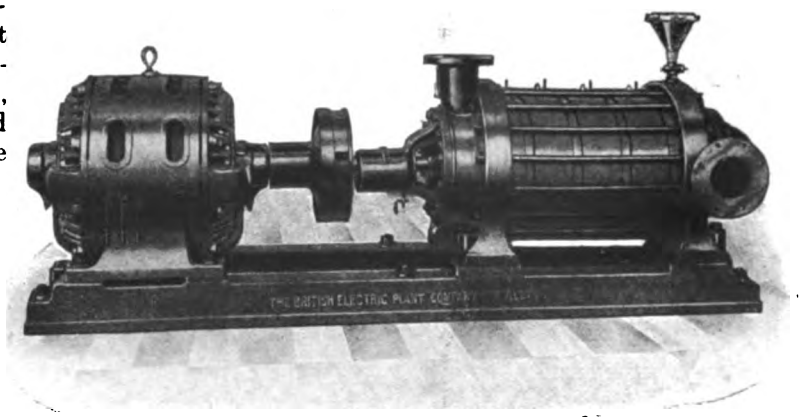

Fig. 3.—B.E.P. Stationary Pumping Set.

therefore be done in a much shorter time than would otherwise have been the case. The B.E.P. Co. have used the system with direct and alternating-current sets with complete success.

We also illustrate (Fig. 2) a vertical pumping set to which considerable interest attaches, as it is arranged to supply a constant quantity of water for condensing purposes from a tidal river, the tidal variation being 14 ft. To enable this to be done economically the speed has to be automatically adjusted by the varying water level, this being accomplished

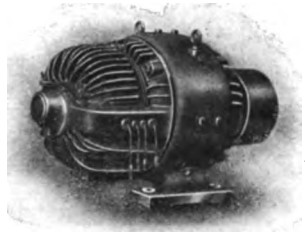

Fig. 4.—Motor for Fiery Mine.

by means of a float system gearing with the shunt regulator of the variable-speed motor. The pump duty is 5,000 gallons per minute against a total head varying from 11 ft. to 25 ft., the motor being of 58 B.H.P. capacity at speeds between 350 to 420 revs. per min.

A.C. Portable Drill.

AN interesting alternating-current portable drill is described in a recent issue of the "Electrical World." The motor is designed to work on a frequency of 60 and at a pressure of either 110 or 220 volts. An indicating control switch for starting and stopping is so placed that it can be operated by the right hand without the hold on the machine being released. Hand hole furnish an easy means of access to the commutator and brushes. The tool will take drills up to $\frac{3}{8}$ in. diameter, and weighs 21 lb. It is claimed that it will drill through soft iron plates and wood at a speed that should ensure its wide adoption in industrial work.

THE ELECTRICIAN INDUSTRIAL SUPPLEMENT.
ISSUED MONTHLY
"THE ELECTRICIAN"
Telegraphic Address: "ELECTRICIAN NEWSPAPER LONDON." Telephone No. 949 HOLBORN.

All communications should be addressed to the Editor, "The Electrician" Industrial Supplement, 1, 2 and 3, Salisbury Court, Fleet Street, London, E.C.

Copy for Text or Advertisement pages for next issue, publishing on **May 27th, 1910,** *should reach the above address by Tuesday,* **May 17th, 1910.**

Manufacturers, Contractors, Central Station Engineers, and those interested in Electrical Industrial Developments are cordially invited to contribute original matter to the SUPPLEMENT, and when suitable this will be inserted as space permits.

Filing Case for "The Electrician" Industrial Supplement.

The INDUSTRIAL SUPPLEMENT is holed for filing, and we are distributing cases which will hold twelve issues. On request a case will be sent to Consulting, Manufacturing, or Contracting firms; to Chief or Resident Engineers of Electricity Supply, Traction or Power Stations; to any firm of Merchants or Agents; to Railway, Tramway, Dock, Harbour, or other companies interested in the applications of Electric Power, &c., to their undertakings; and to other large consumers of electrical energy, either at home, in the Colonies, or abroad.

A portion of each issue of the SUPPLEMENT is reserved for special circulation oversea.

Editorial.

The Progress of Electric Pumping.

In the INDUSTRIAL SUPPLEMENT of March 4, 1910, we pointed out how the development of the petrol-paraffin engine and the dynamo had gone hand in hand till both had reached commercially, at any rate, a state of perfection. Much the same similarity of progress is to be seen in the development of the pump and the electric motor. For while the old reciprocating pump driven by a Cornish beam engine was among the first of the applications of machinery, it was not until comparatively recent years, with the almost simultaneous introduction of the rotary pump and the motor that it began to make decided headway towards its present advanced state.

The reason for the welcome given to the newer state of things is not far to seek. The old type of pumping machinery, with its steam engine and slow moving parts, was practically confined to the ground surface and could not be introduced into the mines or other places it was desired to unwater. Further, such equipment was inefficient, owing to its slow speed and general ponderosity and took up a great deal of room.

General efforts were, therefore, made to design a pump which should better fulfil modern conditions, and this task was made easier by the increasing use of the electric motor for industrial work. The result of these endeavours was soon reflected in the output from makers' works of both rotary and reciprocating pumps, more compact, running at an increased speed, simpler in design, and, above all, suitable for direct coupling to the electric motor. Other results of this dual development are to be seen in the ease of erection, while the charge of the machinery can now be left to comparatively unskilled personnel.

The financial side of the question also showed the great advantages obtainable under the new régime. Much the same arguments can be applied with equal force in this case, and in the other directions in which the motor is being now employed. It is cheaper and more efficient to operate several pumping sets from one power station rather than to supply each pump with its own steam engines. It is easier and again more efficient to run cables down a mine shaft than a steam pipe. It is easier to run and maintain an electric-driven pumping plant in an out-of-the-way corner of a mine than to use a steam-driven set under similar conditions. It is, therefore, scarcely a matter for wonder that the development of the motor-driven plant should have been so rapid.

A point to notice in connection with electric mine pumping is that it is possible by the use of this machinery to work mines which would otherwise be unworkable. The steam-driven pump. for various reasons, could not cope with the flow of water, while the electrically-driven pump with its greater portability was able both to unwater the workings and keep them unwatered.

In the present issue of the INDUSTRIAL SUPPLEMENT we are able, through the kindness of numerous makers, to give some idea of the many ways in which the motor-driven pump is being driven at the present time. In sewage disposal works it is being extensively employed, Birmingham, Maidstone, Burslem and Salisbury being all cities where such a plant is installed, while examples of its application to the unwatering of mines, to fire service and irrigation, will be found in the columns of this issue. The last of these applications should be essentially of interest to the pumping engineer, for in many cases the motor cannot be successfully used owing to the absence of supply mains and other facilities for the supply of energy. There are cases, however, even here, where a large scheme makes the erection of a central power station and the employment of motors a commercial possibility. Examples of this class of work is to be found on the mains of the Northern Colorado Power Co., where an important load is being worked up in the pumping of water for irrigation purposes. The load thus obtained is almost ideal from the central station point of view as it is almost entirely of a summer character, and does not therefore interfere with the winter lighting peak. The motors range from 30 H.P. capacity downward, and are supplied from a 44,000 three-phase line through sub-stations, in which the pressure is stepped down to 2,300 volts for use on the motors. The various farmers concerned are taking up the question with avidity, and much good to both these classes of the population will doubtless result.

We cannot do better than recommend our readers to peruse the various articles in this SUPPLEMENT. They will learn therefrom how much work has been done in the application of the motor to pumping work, and the great strides that may be expected in the future.

The Electric Lighting of Small Towns.

Electric lighting in large towns such as Manchester, Liverpool and Birmingham has now made such progress that any further development will take place along well-defined lines. Flame arc lamps will be used for lighting the main streets, high candle-power metal filament lamps for the smaller streets, and a combination of these two with ordinary candle-power metal filament or carbon lamps for lighting shops, factories and private dwellings. Seeing that this is the case, and that, owing to the extended adoption of the motor car, more and more people are living, though not simultaneously, in both the country and the town, it is at first sight rather surprising to find that more has not been done towards the introduction of the benefits of the electric light into the country or country towns with, say, less than 10,000 inhabitants. Large houses have their own generating plant, as has been amply shown in the last two issues of the INDUSTRIAL SUPPLEMENT, but for the inhabitants of these districts at large there is generally nothing for it but to use, oil lamps or expensive and low quality gas, when some form of artificial light becomes necessary. This state of things is not primarily due to any lack of enterprise on the part of electrical promoters, for it is practically an impossibility to obtain any financial success when such small areas are dealt with under a Provisional Order. The order itself is expensive to obtain, and, when obtained, underground mains and other fitments unnecessary in such areas have generally to be used, to say nothing of other restrictions to cheap supply. The final result is, therefore, that small towns, with few exceptions, are not at present rejoicing in the benefits of the electric light.

Steps are, however, now being taken to remedy this state of things. A company known as the Rural Electricity Supply Co. has just come into being. This company propose to operate without Parliamentary powers, and instead to make their own arrangements with the local authorities concerned. Cheapness combined with safety will be their watchword, overhead mains will be used wherever possible, and great hopes are placed on the efficiency of the metal filament lamp. The erection of a station necessary to supply the communities that are to be dealt with by the Rural Electricity Supply Co. must be governed by economical ideas, so that it seems oil or gas engines would be the natural prime mover to employ, while as the supply would not be continuously available the advantages of this type of plant would become even more obvious.

We wish the new undertaking every success, but at the same time we pray its supporters to order their steps carefully at first, and to choose with discrimination the areas in which they open their first stations. It will be a case of going slowly for some time, but given good finance, low capital outlay, and above all sound management, there is no reason why the scheme should not be a success. There are still plenty of areas where electric lighting is at present unknown, and the new undertaking should do much towards altering a state of things which ought not in these enlightened days to exist. We shall, therefore, hope shortly to see great development in rural electricity supply.

Electrically-driven Pumps and Water Supply.

CONSIDERABLE attention is being given at the present time to electric motor driven pumps for use in connection with the public water supply on main or domestic service, for auxiliary district service at special pressures, and for fire service. Electricity as a motive power has added advantages when operating the rotary or turbine type of pump.

In such plants attention must be called to the remarkably small space occupied and to the insignificant cost of foundations and building compared with a gas or steam reciprocating engine driven pumping station. In fact an electric pump-house becomes a "sub-station" requiring only occasional attendance. Many instances may be found where such plants are now running on both day and night service, and totally unattended except for inspection a few times a week. Frequently, such plants can be self regulated and the supply maintained independent of any adjustment of speed of the plant. On fire service such plants can almost be instantaneously available for action at any time without waiting for the boilers to be stoked up or the engines to be started, while skilled attendance is necessary. In country or small towns with steam operated pumping stations the fire brigade may get to a fire some time before the waterworks can give the requisite supply. With an electric service danger from such a delay disappears. Further, where variable speed motor operation is installed a special fire pressure on the mains can be instantly available if the mains are suitable.

With a pumping station operated from a central electric power station long hour pumping lowers both the running and the first cost of the plant, whereas with a steam or gas engine self-contained pumping station long hour pumping increases the running cost, although the hydraulic friction losses would be reduced on a long hour supply. In many cases long hour running means smaller pump horse-power hours for the same volume pumped than for short hour running.

With an electric pumping plant for water supply service such as that made by the Rees Roturbo Mfg. Co., of Wolverhampton, the electric motor, it is claimed, cannot be overloaded by the pump from variation of pressure or increase of volume, while as the public demand increases the plant adjusts itself to an increase of volume with a slight reduction in head. Owing to the patent revolving pressure drum employed in this type of pump the delivery is absolutely uniform without tremor, thus dispensing with the necessity for relief valves and avoiding water hammer shocks and consequent joint weakening.

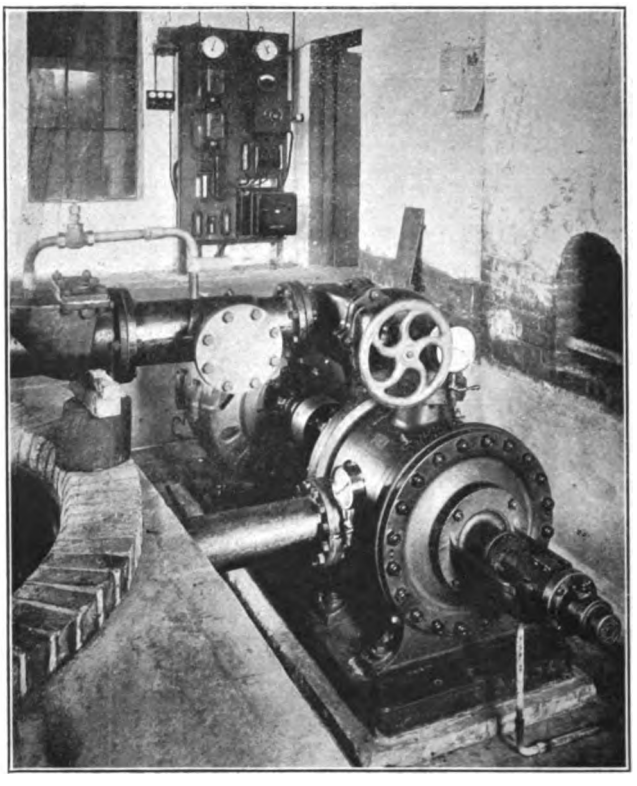

Fig. 1.—Newbury Pumping Station.

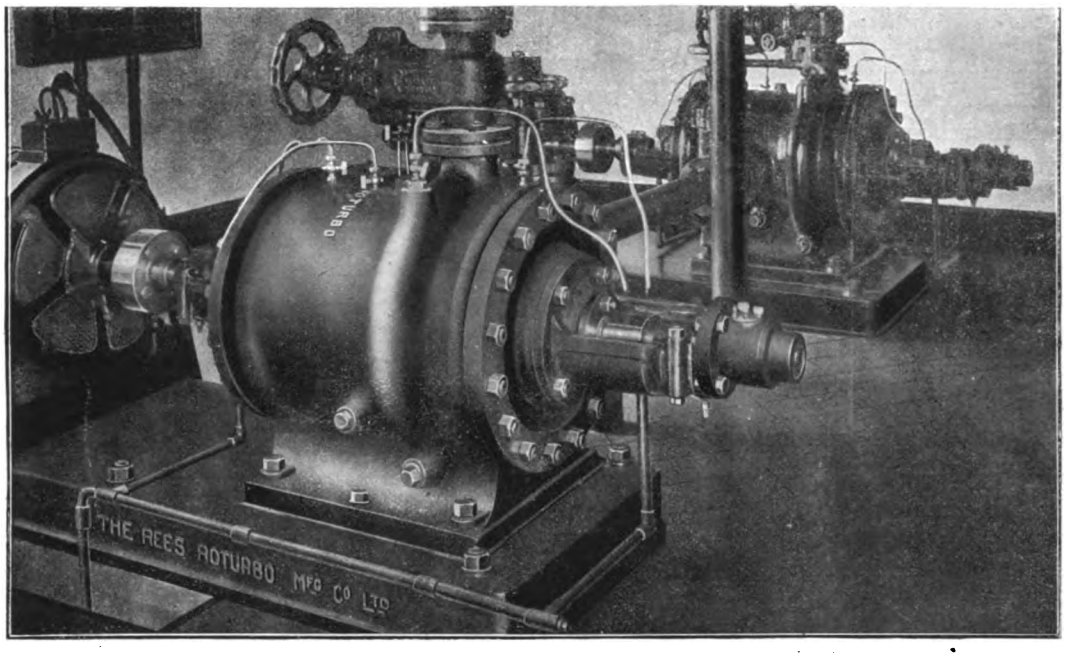

Fig. 2.—Wolverhampton Pumping Station.

A typical country town supply is that at Newbury, Berkshire (Fig. 1), where the water company at first installed one of these equipments as a standby, taking their supply from the local electric supply company. This arrangement was found advantageous from other points of view to such an extent that the town is now regularly supplied from this source. Another motor pump is also to be laid down for duty in an outlying district. The plant in question is capable of delivering 10,000 to 30,000 gallons per hour at pressures between 80 and 50 lb. per square inch. Fig. 2 shows an electrically driven pump installed by the Wolverhampton Waterworks committee to the specification of the engineer Mr. E. A. B. Woodward.

CONSTANT SPEED, CONSTANT POWER, VARIABLE HEAD SUCTION LIFT and VOLUME, HIGH and PERMANENT EFFICIENCY.

THE REES ROTURBO MANUFACTURING Co., LTD.,
WOLVERHAMPTON.

This sub-station at Short Heath, on the outskirts of Wolverhampton, takes its energy supply from the Midland Electric Supply Corpn, the function of the pumps being to provide the requisite pressure for supplying the township of Essington, which is situated at the extreme end of the water area at an altitude which the service reservoir cannot command. The pressure on the inlet side of the pump varies from zero to 40 lb. per square inch, and from 100 to 170 lb. per square inch on the outlet side, according to the time of day and the demand. The pumps have worked day and night without a hitch since January 1909, the station being generally locked up except for an occasional inspection. The old steam plant required two attendants, one for day and one for night, with an occasional labourer for boiler cleaning. The present installation only requires an occasional visit from the local inspector to change over and see to the lubrication. Prior to this installation, the inhabitants were dissatisfied with the intermittent and insufficient supply afforded, and complaints were numerous.

Sewage Disposal Plant at Maidstone. . . . .

SOME time ago the Corporation of Maidstone decided to replace their old sewage disposal plant by an up-to-date installation with electrically-driven pumps, and entrusted Siemens Brothers Dynamo Works Limited. with the execution of the complete installation of the pumping plant. The purpose served by this plant is to pump the crude sewage from the low level at Maidstone to the filter beds. To this end the sewage first passes, on its way to the pump well, through several screens in series, which detain large matter, such as rags, pieces of wood, &c. It is then

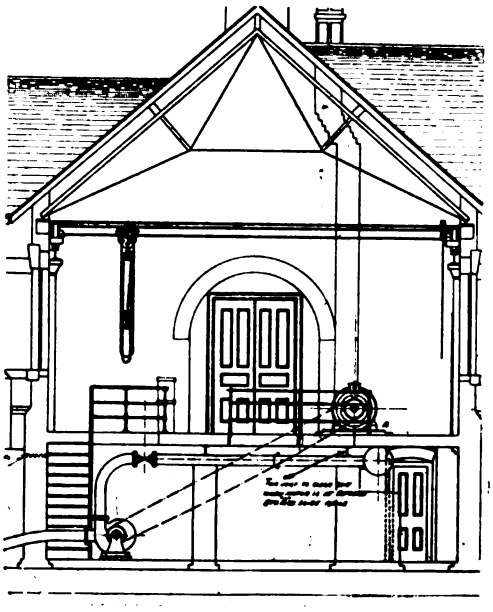

Fig. 1.—End Elevation of Maidstone Pumping Station.

raised by pumps drawing from the above well and delivered into a 24 in. pipe which carries the sewage to the filter beds situated at Aylesford, some 2½ miles below Maidstone, where it is purified, the clean water being returned to the

river. Ordinarily, the material treated is simply crude sewage, and this is dealt with by four 7 in. pumps, but in rainy weather the sewage is diluted with rain water, which

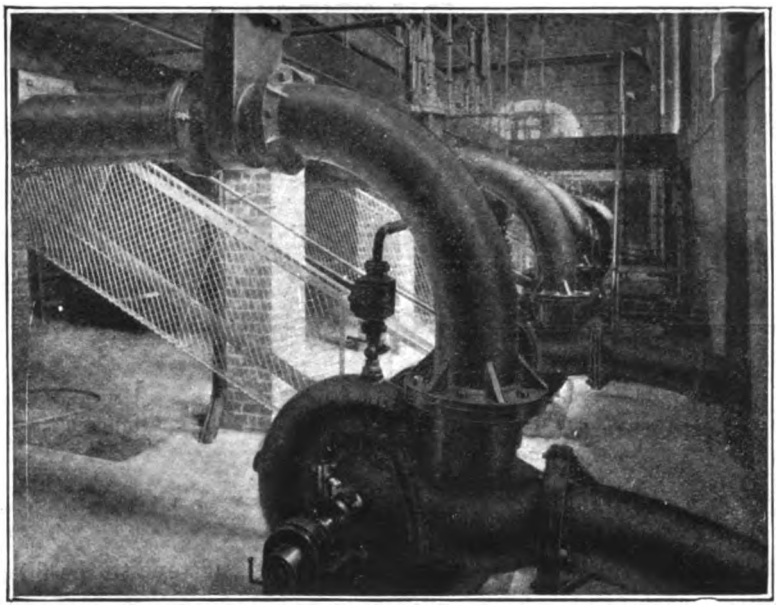

Fig. 2.—The Pumps at Maidstone.

greatly increases its volume, and the above pumps are then assisted by three larger ones of 9 in. diameter, which discharge on to the storm water filter beds situated close at hand and built on the river banks.

The screens are installed in a separate house near to the pumping station. They are lowered through openings in the floor, and each screen is provided at its lower end with a broad ledge on which the material which cannot pass through the screen is deposited. From time to time the screen is hoisted until the ledge is on a level with the floor, and the deposits removed. The raising of the screens is performed with the aid of a small travelling crane which is operated by a Siemens motor. The span of the crane is 19 ft. 9 in. between rail centres, and the lifting capacity is 2 tons. The travelling and traversing motions are operated from floor level. The lifting speed of this crane with a load of 2 tons is 20 ft. per minute.

Fig. 3 shows the general arrangement of motors and pumps, &c., in the pumping station. The motors are fixed to the concrete floor and drive the pumps in the basement by belts. The pumps are primed by two small charging sets, each consisting of a small centrifugal pump driven by a 7 B.H.P. motor running at 1,000 revs. per min. The water is circulated through an ejector by a closed system of pipes, which creates a vacuum above the sewage pumps and in consequence sewage is drawn up. After the pumps have thus been charged the main driving motors are started up. The arrangement of the piping between the two charging pumps and the sewage pumps is such as to allow either ejector to charge any of the pumps, or both ejectors to work together to shorten the time of charging. Each of the four centrifugal crude sewage pumps is capable of delivering 150 cubic ft. of sewage per minute against a total head of about 31½ ft. when running at 800 revs. per min. This total lift includes the loss of head due to friction. The three storm water pumps are capable of delivering 225 cubic ft. of sewage per minute against a total head, including friction, of about 21 ft. Each of the seven pumps is driven by a Siemens ventilated shunt motor with commutation poles, having an output of 20 B.H.P. at a normal speed of 750 revs. per min. The speed can be increased by a switchboard type field rheostat up to a maximum of 825 revs. per min. Current is obtained from the Maidstone Corporation supply mains, the voltage being 2×230 volts. The sewage pump motors are connected across the outers, while the two small charging motors mentioned above are connected between the inner and one of the outers. The motors are started up by Siemens protected type starters fitted with over-

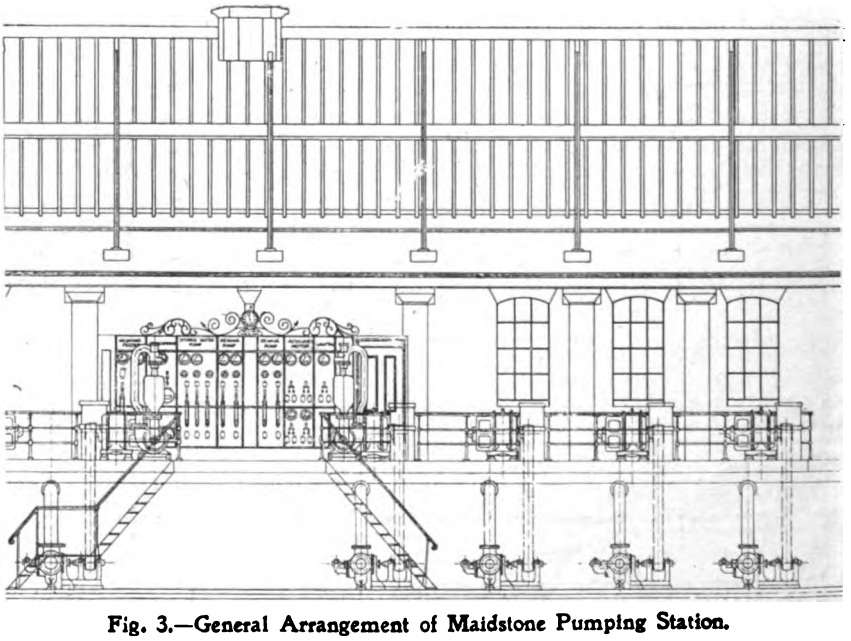

Fig. 3.—General Arrangement of Maidstone Pumping Station.

Digitized by Google

load and no-voltage releases. They are fixed to the railings near to their respective motors, as will be seen from Fig. 4. The switchboard is of slate, and consists of the following panels: One feeder panel for two incoming feeders, one integrating panel, one storm water panel for three motors, one sewage pump panel for four motors, one panel for the small charging motors, and one lighting panel for two 230 volt lighting circuits. The panels are fitted with all necessary control and measuring instruments, including main switches, voltmeters, ammeters, watt-hour meters, &c.

Fig 4.—The Switchgear at Maidstone Pumping Station.

The hand-operated travelling crane in the pump house has a lifting capacity of 2 tons and a span of 24 ft. 10 in. between rail centres. To provide for the fire service and general water supply to the station, there is installed in the screen house a 2 in. centrifugal pump driven by a 5 B.H.P. motor. This pump has a capacity of 80 gallons per minute against a head of 62 ft. The plant has now, we understand, been running for several months with entire satisfaction.

Oerlikon Portable Electric Hand Drilling Machines.

THE Maschinenfabrik Oerlikon, whose London offices are at Oswaldestre House, 34, Norfolk-street, Strand, where the British, Irish and Colonial department is under the management of Mr. G. Wüthrich, have recently issued very complete illustrated descriptive price lists of the firm's specialities in portable electrically-driven hand drilling machines.

From the range of apparatus shown in these lists it is evident that the firm have given great attention to the requirements of the trades which use such drills. The drills are of very neat design, and the spindle of the machines is directly driven by an electric motor. The hand drilling machines (without speed reduction), when equipped with two-phase and three-phase motors, are built in two sizes, fitted with motors of $\frac{1}{16}$ H.P. and $\frac{1}{8}$ H.P. respectively, and are specially adapted for drilling holes of from $\frac{1}{4}$ in. to $\frac{3}{8}$ in. diameter in iron, the weights of the drills being 11 lb. to 19 lb. respectively. The direct-current hand drilling machines are equipped with motors of $\frac{1}{8}$ B.H.P. and have a weight of 22 lb. They are suitable for drilling holes up to $\frac{3}{8}$ in. diameter in iron and up to $1\frac{1}{2}$ in. diameter in white or hardwood. The machines can also be equipped with single-phase motors

Hand drilling machines with a single speed reduction are specially built to drill holes, say, from $\frac{3}{8}$ in. to $\frac{3}{4}$ in. diameter in iron. The speed of the motor is reduced by means of a simple cased-in gear. The drills can either be equipped with a breast plate or with a screw and hand feed wheel; the breast plate is easily removable. The machines are equipped either with ordinary fixed handles or with tubular handles. In the machines fitted with ordinary fixed handles the current can be cut off by means of the right-hand side handle, whilst those with exchangeable tubular handles have the

Digitized by Google

current circuit completed by means of a tumbler switch. The drill spindle is furnished, as a rule, with a Morse cone (No. 2), so that ordinary drills may be used. In Figs. 1 and 2 are illustrated typical Oerlikon drilling equipment.

In many industries, where a great variety of holes have to be drilled in soft or hard metal, it is necessary for the satisfactory execution of these duties to employ drills with different drill speeds, and to meet these demands the Oerlikon Co. supply their universal hand drilling machines with three different speed steps, the latter obtainable by means of three mechanical speed reduction gears cased into the shell of the machine, and operated by means of a simple lever. The machines are suitable for drilling holes from $\frac{1}{8}$ in. to $\frac{3}{4}$ in. diameter in iron, and of considerably larger diameters in softer metals or white and hardwood. The speeds of the drill spindle are as follows: With direct-current motor,

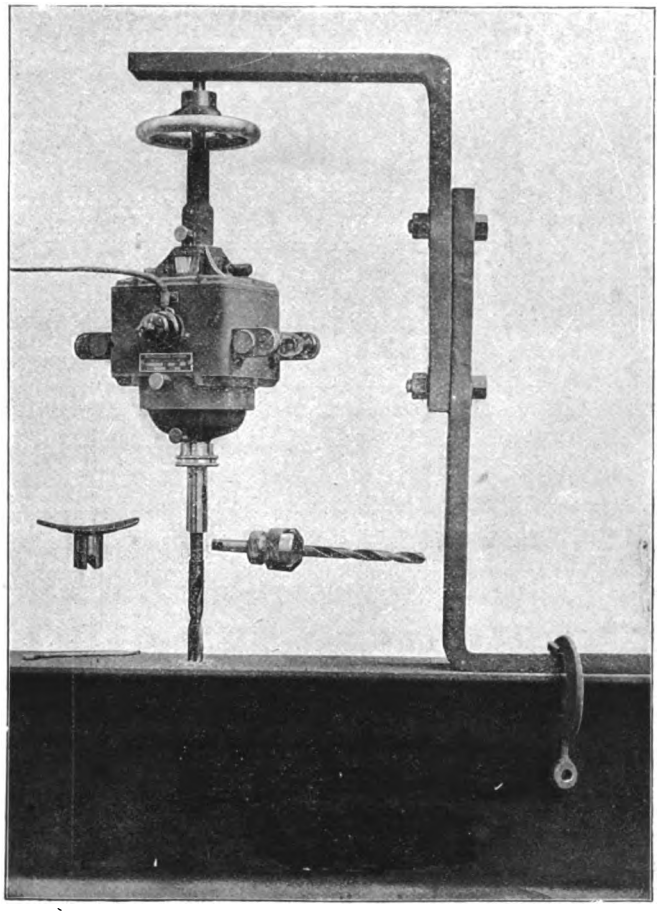

Fig. 2.—Oerlikon Drill at Work.

850, 650 and 350 revs. per min.; with two or three-phase motors, 870, 520, 330 revs. per min.

These drilling machines, with three different speed steps, are also adapted for fixing to a standard with movable work table. In this form they can be regard as portable quick drilling machines, independent of all belt driving, gearing, &c. The standard or column is made of cast steel, and is carried in a clamp bearing on the base of the work table, readily movable in all directions. The table has two T grooves for securing the work, the vertical movement of the work table being actuated by means of a rack and hand lever. The diameter of the work table is 12 in., the maximum height between head and work table $8\frac{3}{4}$ in., the maximum lift of the table 4 in., the vertical movement of the standard or column 6 in., the distance between the centre of the stand and the centre of spindle 10 in., and the weight of standard and table about 175 lb.

The "Hatfield" Pump.

A PUMP is a many-sided piece of apparatus. It can be used, considering water as the sole fluid in question, for water supply, for fire protection, for pressure augmenting, for irrigation, for spraying, for drainage and for boiler-feed purposes. If other fluids be taken into consideration its uses are just as many and varied. For certain special purposes particular types of pump are best suited, while, on the other hand, some types of pump seem specially suited for practically every kind of work. In this latter class may certainly be placed the "Hatfield" pump, made by Messrs. Merryweather & Sons, of Greenwich. It has besides the advantage to intending users of having been tried in practice under widely varying conditions, but with constant success.

The principle of the "Hatfield" pump is the following: Three pump barrels are arranged symmetrically round the motor shaft. These barrels form part of a single casting in which are also placed the valve chambers and passages. Each pump piston is of comparatively large diameter, though the stroke is short. The pump is, therefore, specially suitable for direct coupling to a motor, as it can be run at high speeds. The valves used are of indiarubber, and are of ample area though small lift. A bye-pass is fitted to facilitate starting.

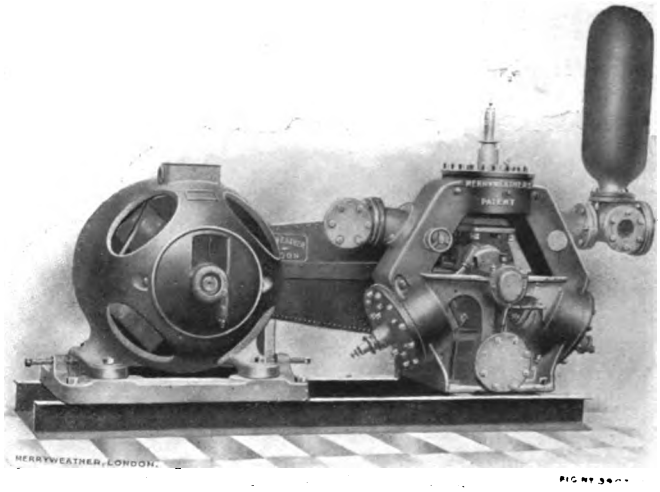

Fig 1.—Electrically-driven "Hatfield" Pump.

Turning now to the applications of such a pump, its great simplicity makes it specially suitable for use in connection with the water supply to country houses or with the fire precautionary arrangements in buildings where a skilled fitter is not employed. Fig. 3 shows such a pump direct coupled to an electric motor, the combination being exceedingly neat and compact. The particular set illustrated was supplied by Messrs. Merryweather to an estate in Leicestershire for use in connection with both the domestic water supply and the fire protection arrangements. The pump is said to be silent in working, so that it can be placed and worked in the basement without annoyance to the neighbouring householders.

This type of pump finds a useful application at Messrs. W. H. Smith & Son's premises in Kingsway, where a novel fire service was carried out by Messrs. Merryweather. A "Hatfield" pump driven by a motor is placed in the basement and connected with a fire main system which extends throughout the building, the necessary hydrants and hose being fitted on each floor. The pump can be started auto-

Digitized by Google

matically, and all that it is necessary to do on an outbreak of fire is to run out the hose at the nearest hydrant. The pump will thus be started, and a powerful jet can be played on the flames almost immediately.

Besides directly-coupled sets Messrs. Merryweather also supply the "Hatfield" pump driven by a motor through a silent chain. A combination of this kind, which was supplied to the Great Eastern Railway Co. for use in the fire protection of Parkeston Quay, Harwich, is shown in Fig. 1. The pump is of the patent "Hatfield" type, having three plungers arranged 120 deg. apart around a common crankshaft. No barrels are fitted, the gunmetal plungers working through packed glands directly in the valve chambers. This arrangement, it is claimed, gives a minimum clearance between the plungers and the valves, thus enabling the pump to be used on a deep lift. The plungers are $7\frac{1}{2}$ in. in diameter and the stroke is $5\frac{1}{2}$ in. Each plunger is fitted with a substantial tail-rod working through a stuffing box in the valve cover; solid grease screw-down lubricators are fixed at the extremities of these rods, the tail-rods, plungers, connecting rods and crank being drilled to give thorough lubrication. The crankshaft is, as usual, run in adjustable gunmetal bearings with long wearing surfaces and oil reservoirs, and the connecting rods are coupled to the plungers with large ball and socket joints. The pump is capable of delivering 500 gallons of water per minute when running at a speed of 220 revs. per min.

The pump is driven from an electric motor by means of a silent chain, $6\frac{1}{4}$ in. wide, enclosed in a dust-proof and oil-tight case. The electric motor is shunt-wound, of 52 B.H.P., and is provided with large ironclad switch and "fool-proof" starter. The pump and motor are mounted on a channel iron frame, while the motor is on slide rails, in order to allow of the tension on the driving chain being adjusted. The machine is designed to give a maximum pressure of 100 lb. per square inch at the pump. It is fixed at the quayside, and a connection is made from the delivery to a 6 in. cast-iron main, which is laid round the quay, and upon which hydrants are fixed at suitable intervals. In addition to this there is an independent connection for hose direct on the pump, for coping with fires in the immediate neighbourhood. The suction is taken from the river through a 6 in. cast-iron pipe about 60 ft. long, the lower end of this pipe being fitted with a foot valve and strainer. The maximum lift at low water is 24 ft. As may be seen from our illustration, the installation is very compact, considering the quantity of water delivered.

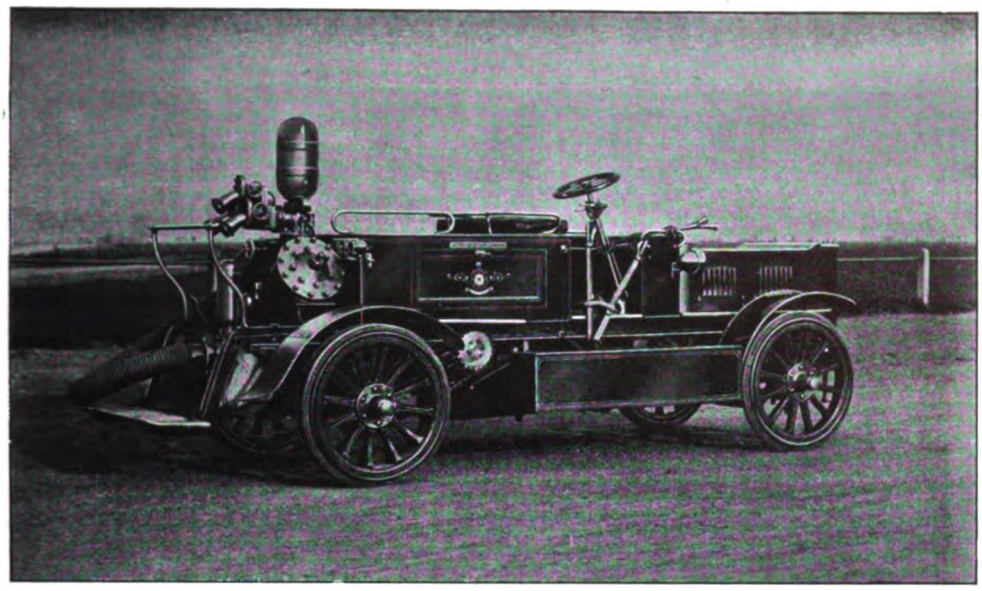

Fig. 2.—Merryweather Motor Fire Engine.

It is often rather an advantage from a domestic point of view to be able to alter the stroke of the pump. For instance, when running on short stroke a pump of this kind made by Messrs. Merryweather is capable of forcing water through long lines of pipes or to great heights, while when the stroke is made longer large quantities of water can be thrown with great force on the fire. The variation in stroke is effected by means of a sliding eccentric, provided with internal gearing for adjusting the eccentric relative to the crankshaft, thus altering the amount of stroke. A hand wheel is provided for the purpose of adjusting the stroke, which can be done gradually, thus enabling any desired quantity or pressure to be obtained.

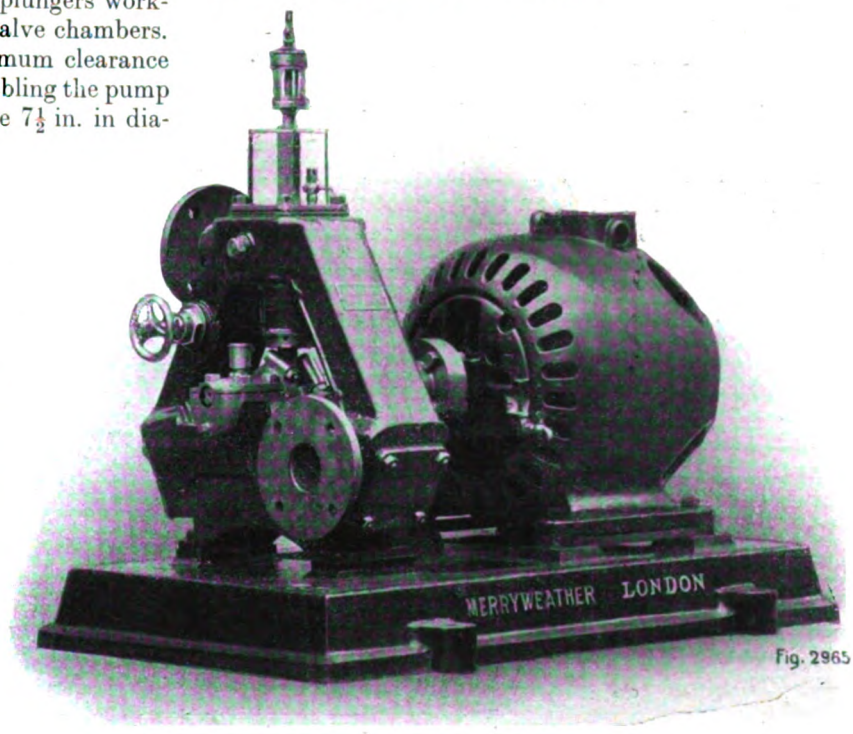

Fig. 3.—Merryweather Direct Coupled Motor Pump.

Another interesting piece of equipment is the electrically-driven pressure augmenter, of which an example is in use at Mr. Alfred de Rothschild's London house. The fire main is carried

Digitized by Google

up to the roof, where a large tank is connected to it. This tank is filled from the waterworks' main through a ball valve, and a reflux valve is fitted to the fire-main pipe, so that when

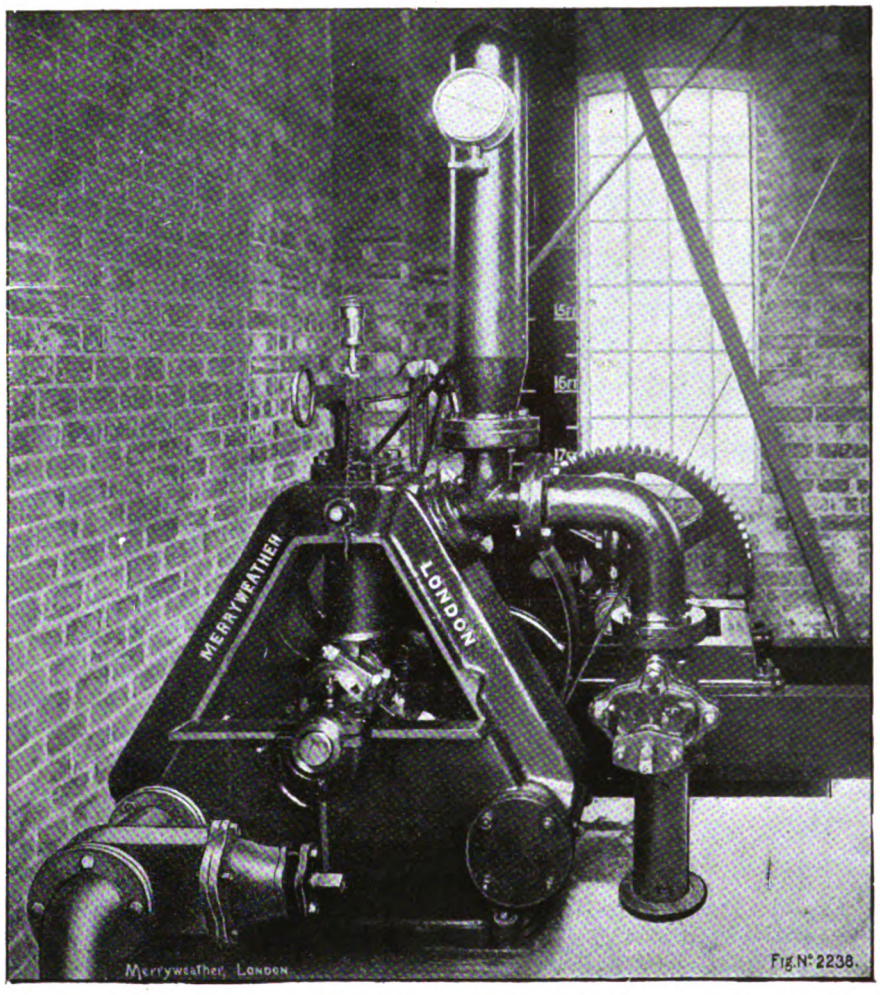

Fig. 4.—"Hatfield" Pump at Easton Lodge.

the pumping apparatus increases the pressure the water cannot return to the tank, but supplies the hydrants placed on each floor. The pump, which is of the "Hatfield" treble-barrel type, driven by an electric motor, is placed in the basement and takes suction from the roof tank. The starting switches and resistances are placed near by, and an ingenious float arrangement, working in a small tank placed over a large one on the roof, is used to operate the main switches. By this device there are no heavy cables carried through the building. When a fire occurs and the hydrant is opened the smaller tank empties into the fire main, the float falls and the pump automatically starts work. As soon as the hydrants are closed again and the tanks fill up, the float rises and the pump stops. A relief valve with the delivery into the smaller tank is provided, so that no damage will occur to the fittings between the time the hydrants are closed and the pump ceases to run.

In what is said above we have endeavoured to give some examples of the ways in which the "Hatfield" pump may be employed to provide us with what are generally known as the "benefits of civilisation"—that is, with the things we should find it very inconvenient to do without. The "Hatfield" pump can, however, also be used for deep well work and other high lifts, while besides being fixed it can be made portable, and where water power is available it can, in turn be converted into a generator and used to drive farm machinery. Among the portable sets manufactured we may mention some very useful electrically-driven bilge pumps, which should find a wide application in dockyards for keeping vessels clear of water after launching and for clearing the compartments after testing. It would not, of course, be seemly to mention the name of Merryweather without referring to their well-known fire engines whose pumps certainly come under the heading of portable. These pumps are carried on boats and road vehicles, and with the introduction of the motor car opportunity has been taken to use the petrol engine both for working the pump and driving the car. Such an equipment, which is called the "Hatfield" motor fire engine, is shown in Fig. 2. This engine was constructed by Messrs. Merryweather for the Rochdale Fire Brigade, and was the first machine of its kind to be put into service in England. It is fitted with a 50 H.P. four-cylinder petrol motor, and this engine propels the apparatus, and also drives a treble-barrel "Hatfield" pump, capable of delivering 450 gallons of water per minute. The speed on the road is from 20 to 30 miles an hour, and the pump can be brought into service instantly on arrival at a fire. At the official tests at Rochdale the pumping and road-running capabilities of the machine were effectively demonstrated. Its climbing and braking powers were tested by a trip over Blackstone Edge, and a pumping display was afterwards given on the Cattle Market ground. Motor fire engines of this pattern have also been supplied to several other leading fire brigades, including London, for which two machines are in actual service and two others nearing completion. It will therefore be seen that with their "Hatfield" pump Messrs. Merryweather cover a large field of application very satisfactorily.

Heenan & Froude Fans.

A FIRM who are justly noted for their fan work, and who may certainly be considered among the pioneers in this branch of engineering industry, are Messrs. Heenan & Froude, of Manchester. The apparatus turned out by them for ventilating and blowing include numerous types; low, medium and high-pressure fans are made, and, in fact, any operation requiring forced ventilation can be carried out by means of one at least of their fans. In this article we describe some standard equipments which have been laid down by Messrs. Heenan & Froude, and which show the class of work carried out by this firm.

The Heenan high-pressure fans are made in all sizes, from 12 in. to 28 in., and are capable of delivering from 400 to 4,000 cubic ft. of air a minute at pressures up to 24 in. water gauge. Such fans as these are specially designed for supplying air to cupolas, smiths' fires and other similar apparatus. The medium-pressure standard blast fans are turned out, varying in diameter from 9 in. to 28 in.

and delivering 500 to 5,000 cubic ft. of air a minute at water gauges from 9 in. to 16 in. These fans are also specially adapted for smithy work, and as many as 40 fires can be supplied from one of them. A fan installation recently supplied to the Buxton electricity works is of interest; it is fitted in the engine room and is direct-coupled to a high-speed engine. This fan delivers 7,000 cubic ft. of air a minute. The engine which drives it is of the high-speed totally enclosed type, fitted with forced lubrication, and the destructor to which it supplies air is also Messrs. Heenan & Froude's special design. An electrically driven fan of this type, is used for supplying forced draught to another refuse destructor at the electricity works at Bury St. Edmunds. This fan supplies 5,000 cubic ft. of air a minute at a water gauge of 4 in. while another set of these fans have been supplied for ventilating the underground railways in London. Each of these fans is capable of delivering 18,000 cubic ft. of air a minute at a water gauge of 1·7 in. and is fitted in chambers in the roof of the tunnel and extract the air from the tunnel and afterwards force it through grids opening into the street above.

Some Examples of Mather and Platt Pumps.

THE adaptability of the electric motor to pumping work is, as we have endeavoured to show in another column, very great. With very little change in design, it can be used in a variety of places and is equally satisfactory in all of them. This point is well brought out in the following description of the ways in which Messrs. Mather & Platt's pumping sets have been employed.

Fig. 1.—Main Pumping House at Burslem Corporation Sewage Works.

Digitized by Google

The first example is that of the low-lift turbine pumping plant supplying circulating water to the cooling towers at Salford Electricity Works. This cooling plant requires 750,000 gallons of water to be circulated per hour at full load, and this quantity is dealt with by the four Mather & Platt patent turbine pumps shown in Fig. 2. Each of these pumps is direct coupled to and mounted upon the same base as a direct-current steel-clad semi-enclosed motor made by the same firm, the couplings being of their special flexible type. The bodies of the pumps are of cast iron with specially arranged branches to suit the conditions of the piping. It will be noticed from the illustration that the suction branch divides into both sides of the pump allowing the water to enter on both sides of the impeller; thus the pump is in perfect balance. The water is discharged from the impeller into specially designed guides, allowing it to pass into the whirlpool chamber without shock. Each pump deals with 250,000 gallons per hour against a total head (including 10 ft. suction and

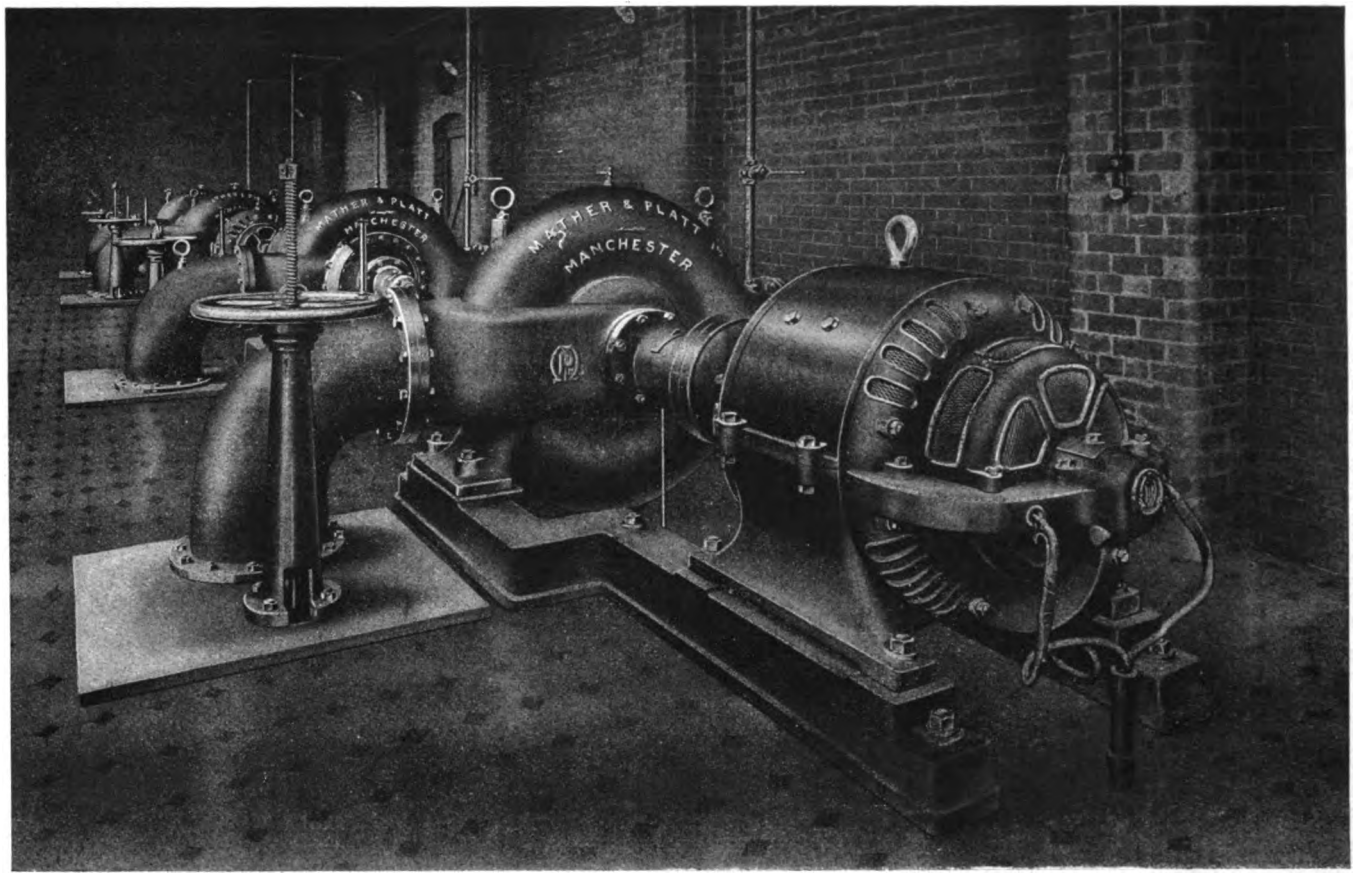

Fig. 2.—Mather & Platt Turbine Pumps at Salford Corporation Electricity Works.

calculated friction in piping) of 30 ft. when running at a speed of 450 to 500 revs. per min. Special bearings carried from the pump casing and quite independent, having no connection with the water, are provided. On both sides of the pump where the shaft passes through the casing water-sealed glands are provided to prevent air leakage.

The motors are each of 60 B.H.P. of the four-pole type compound-wound for 460 volts. Suitable starting pillars were supplied by the same firm, and the connecting cables from the starters to the motors are taken underground. A small low-lift pump of similar type, delivering about 33 gallons per minute against a head of 16 ft. running at a speed of 1,400 revs. per min., is provided for priming the main pumps.

Another example of this firm's work is the pumping plant at Falconbrooke Pumping Station, Battersea. This consists of three large Mather & Platt pumps each designed to deliver 13,333 gallons of storm water per minute to a height of 16 ft., the pumps being driven by large vertical gas engines to which they are direct coupled but mounted upon independent baseplates. The pumps are provided with brass air priming gear and hydraulically operated sluice valves. The suction handle to each pump is of the double type, entirely balancing the impeller and giving ample water-way. These pumps were manufactured to the usual strict requirements of the London County Council engineers.

The pumping plant at the Birchenwood Colliery forms a portion of a very large and complete electrical pumping plant carried out by Messrs. Mather & Platt. Steam is taken from existing Lancashire boilers to high-speed steam engines and Mather & Platt generators provide three-phase current at 2,600 volts at a frequency of 50 cycles.

The cable down the pits is of ample size. It is of the three-core type insulated with solid bitumen and double wire armoured. It is supported in the shaft by substantial cleats. In one shaft, known as the No. 18 pit, there is a pump of a capacity of 500 gallons per minute of the five chamber type which is driven by a squirrel cage motor of 130 B.H.P. capacity. This pump delivers against a total head from all causes of about 500 ft. Working in-bye is a small pump for dealing with water brought over from another pit and which has a capacity of 500 gallons per minute at a speed of 1450 revs. per min.; this is direct coupled to a three-phase motor of 27 B.H.P. In the shaft known as the No. 4 pit are three large pumps. The first of these deals with water brought over from another shaft and has a capacity of 400 gallons per minute and at a total head of 400 ft. 1450, revs. per min. The motor is interchangeable with the large motor already mentioned and is of 130 B.H.P. A special feature of this pump is that it is made entirely in a special quality of phosphor bronze to enable it to deal with the water which is exceedingly acid.

136, GOWER St., & 24, Gower Place, LONDON, W.C.

The two further pumps in this pit are of a special type made by this firm for dealing with large heads. Each is of the six chamber type having a capacity of 800 gallons per minute against a total head of 900 ft. running at 1,475 revs. per min. The pumps are driven by motors of 375 B.H.P. with wound rotors. Suitable switchgear is provided for the whole of the above pumps. All this equipment was supplied and erected by Messrs. Mather & Platt. in accordance with the specification issued by the agent of the colliery.

The application of the electric motor to sewage pumping will be well illustrated by the equipment supplied by Messrs. Mather & Platt to the Burslem Corporation. This system includes, besides the usual tanks, distributing chambers, storm-water beds and filters, two interesting pumping plants situated respectively on the low and high levels. In the low-level pump house (Fig. 3) are six 3 in. diameter low-lift turbine pumps each direct coupled to a 1½ B.H.P. protected type shunt-wound steel-clad motor, wound for 440 volts and running at 1,290 revs. per min. with a 10 per cent. increase of speed. Complete starting and regulating switchgear is also provided. Each pump is capable of delivering 125 gallons per minute against a total head of 16 ft. including friction. The pumps are arranged in two groups of three pumps in each ; one group is used for lifting the low-level sewage from the low-level sump well, and discharges into the main high-level culvert prior to entering the screening and detritus tanks. Each pump has a 3 in. suction pipe fitted with gunmetal-faced sluice valve, and is coupled up direct to one common 6 in. suction pipe fitted with a screw-down foot valve. The delivery branches are coupled up to one common 6 in. delivery pipe. The second group is used for lifting the low-level storm water from the low-level sump well, and delivers into the main high-level feed carrier prior to its entering the storm beds. The piping is arranged in a similar manner to the low-level sets.

To each sump well is attached a special alarm and indicating apparatus, which operates with the flow, ringing a bell to call the attention of the man in charge, and at the same time indicating whether another pump is to be started up or one stopped. The priming of these pumps is affected by means of a feed pipe taken from the rising main of the main pumps.

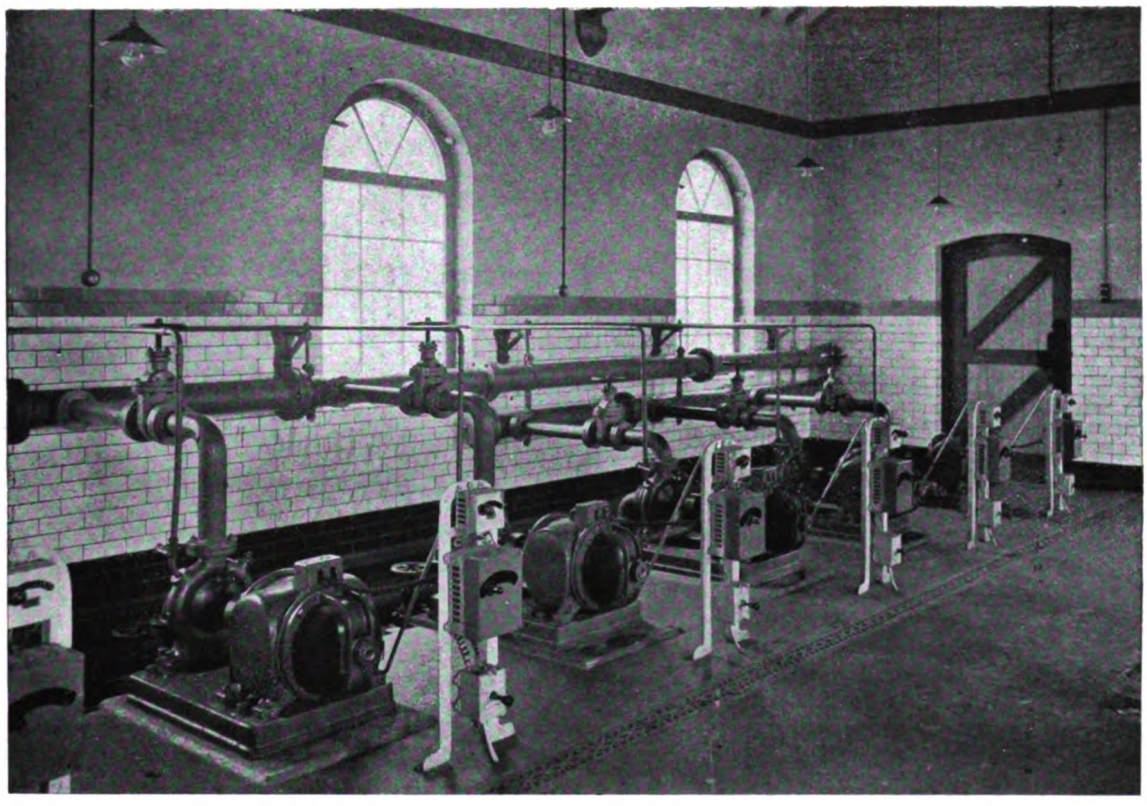

Fig. 3.—Electric Motors in Low-Level Pump House at Burslem Corporation Sewage Works.

The plant in the main pump house consists of: One 9 in. diameter patent turbine pump direct coupled to a 30 B.H.B. protected type shunt-wound steel-clad motor, wound for 440 volts and running at 775 revs. per min. with a 10 per cent. increase of speed, provided with complete starting and regulating switchgear. This pump delivers 1,390 gallons per minute against a total head of 35 ft. and has 9 in. diameter suction and delivery branches each fitted with a gunmetal-faced sluice valve. Two 6 in. diameter patent turbine pumps, each direct coupled to a 16½ B.H.P. protected type shunt-wound steel-clad motor with switchgear and wound for 440 volts, and running at 1,100 revs. and 10 per cent. increase of speed. Each pump delivers 695 gallons per minute against a total head of 35 ft. and

has 6 in. diameter suction and delivery branches each with gunmetal-faced sluice valves. These three pumps are attached to the main suction pipe starting from 6 in. diameter and tapering to 15 in. diameter, where it then falls 12 ft. into the sump well and is here provided with a horizontal type foot valve. The delivery main also tapers from 6 in. diameter to 15 in. diameter, and then opens into a 21 in. diameter rising main. These pumps are primed from this rising main.

This pump house is also provided with special automatic alarm, indicating as previously described, and the plants run continuously throughout the 24 hours.

"Fielding" Oil Engines.

A POINT to which attention may be called in connection with a number of engines working on the Otto cycle is that they require no external heating once they are started, and therefore are raised to a level of those machines working on electrical ignition. In fact, their "self-containment" is even rather greater, for with electrical ignition accumulators may run down, while with a self-contained engine of the kind we are describing, as long as the engine is hot enough the charge will explode—the very fact of the explosion taking place causes the engine to remain hot enough.

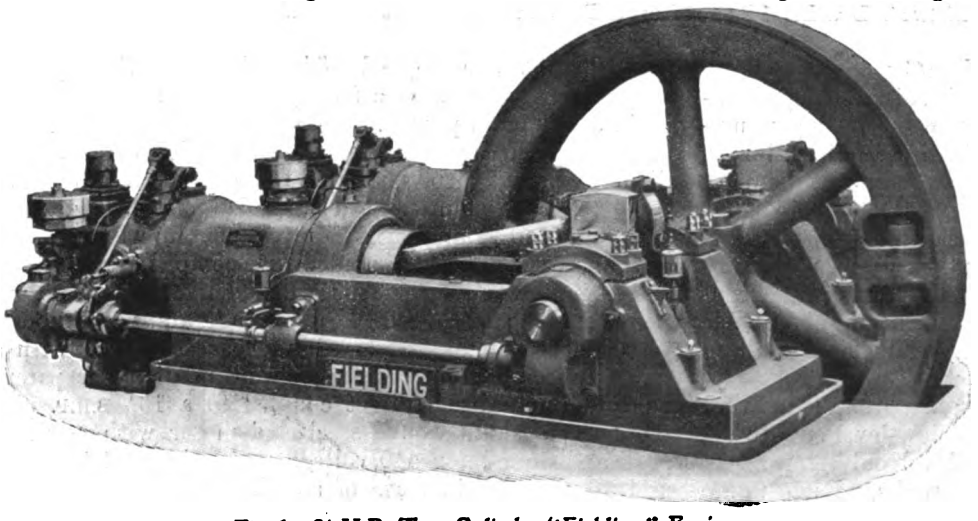

Fig. 1.—2½ H.P. Two-Cylinder "Fielding" Engine.

Messrs. Fielding & Platt, of Gloucester, have for some years been manufacturing the "Fielding" lampless oil engine, which works on the Otto principle. It is claimed for this engine that it fulfils all the requirements of a cheap, safe and handy motor, suitable for all purposes, and that in places where gas or steam cannot be conveniently used it will be found invaluable. It is economical in operation, the oil consumption being ⅛ pint per horse-power-hour, while, since it requires but little attention, the wages bill is reduced to a minimum.

Fig. 1 shows the standard 2½ H.P. "Fielding" engine, which finds a wide application in both country house and industrial work. Its capacity is sufficient to light a fair sized house, especially since the introduction of the metal filament lamp, while it can also be conveniently employed in driving, sawing, pulping or chaff-cutting machines. Similar standard engines having an output up to 60 H.P. are also made, while larger sizes can be obtained if desired.

It is claimed that 10 minutes' external heating is required to render the engine hot enough for starting and that the lamp can then be wholly removed. The speed is controlled on the "hit-and-miss" principle by means of a ball governor—a principle which is preferred by the makers to

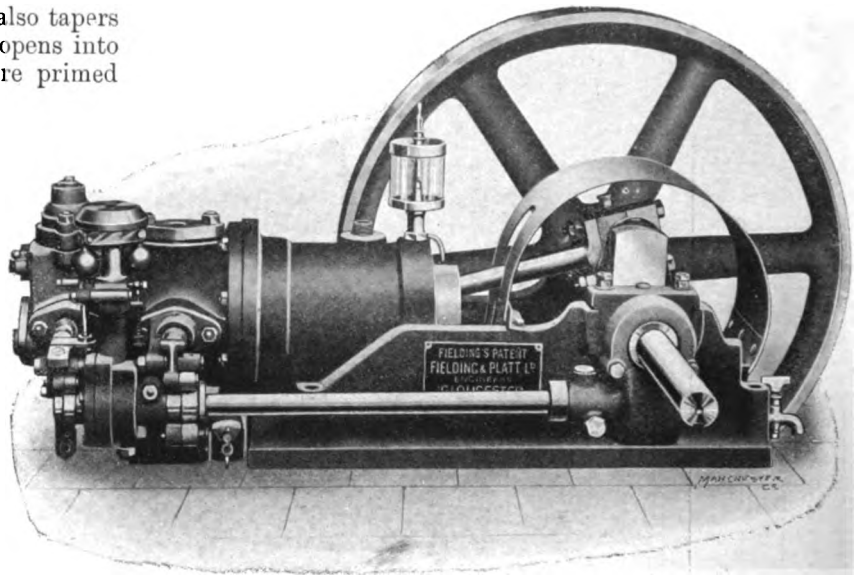

Fig. 2.—Portable Type "Fielding" Engine.

that of varying the force of the explosions, whilst it is found to be just as effective, the variation from no load to full load being only from 2 to 3 per cent. Once started, the engines are capable of being left all day long without attention.

"Fielding" engines of the one-cylinder type are made in 12 standard sizes, varying in output from 2½ H.P. to 60 H.P., while larger sizes up to 120 H.P. are fitted with two cylinders.

Turning to applications we illustrate in Fig. 2. a portable engine which, we understand, can easily be applied to the driving of farm machinery. This engine has a water-cooling tank. The illustration (Fig. 2) shows the latest type of portable oil engine, with water-cooling tank fixed underneath, which has sufficient capacity to run all day. The oil tank also contains sufficient for a day's run. The wheels are of

Digitized by Google

specially large diameter, of wrought iron, made to "track," and very suitable for rough travelling. Driving pulleys can be fixed on either side of shaft to suit convenience of driving. It can be worked in all weathers, as after starting there is no lamp to blow out.

These engines are gradually replacing portable steam engines for agricultural and other work, the economy in fuel and attendance being very considerable. They are made in four sizes, of 7½, 9½, 11½ and 16 B.H.P. capacity. The "Fielding" engine is, it is claimed, an ideal motor for this class of work, being light, easy of transport, and self-contained, while it carries sufficient oil for a full day's run. The engine, when once started up in the morning, after being oiled round, does not require the attendance of a man, but can be left running, which means a considerable saving.

Control of Electrically-driven Pumps.

THE constantly increasing use of the electrically-driven pump has been, is, and will be undoubtedly assisted by the present excellence and reliability of automatic electric motor control apparatus. The "Igranic" automatic motor control apparatus manufactured by Adams' Mfg. Co. of Bedford, has solved many problems connected with the control of pumping machinery, which otherwise would have presented great difficulties, more especially where remote control of the motor was essential. This firm make automatic controllers for the smallest to the largest sized pumps, for direct or alternating current motors, for all voltages and all types of pump. The usual starting set for direct-current pumps driven by a motor whose horse-power does not exceed 20 is shown on Fig. 1. This consists of a solenoid operated starter, having mounted on the same slate base a magnetically operated main switch: a single-pole float switch operates this set to start and stop the motor. When the water falls to a predetermined level the float switch is thrown over and makes an electrical circuit. This in turn causes the magnetic main switch to close, and the starter correctly starts the motor driving the pump; when the water reaches the desired level the float switch "throws back" and causes the magnetic main switch to open and so stop the motor. All current making and breaking is thus taken by the main switch, which has a powerful blowout, and will rupture the fiercest arc.

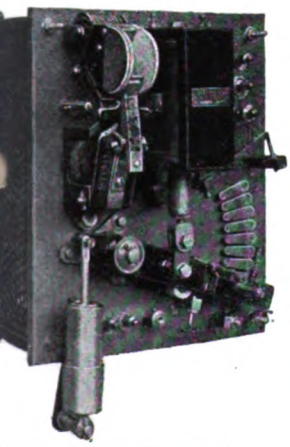

Fig. 1.—Adams Automatic Starter for Pumping Work.

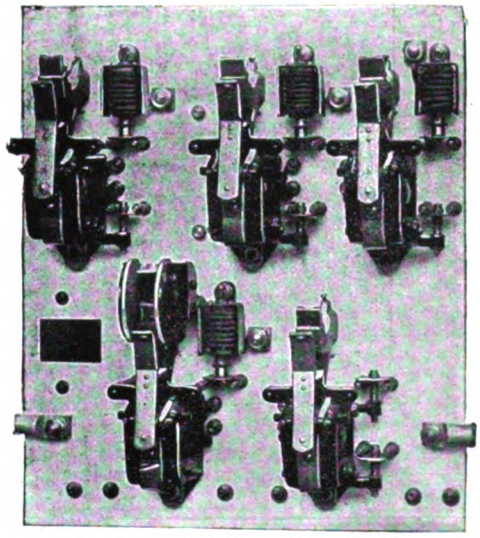

Fig. 2.—Adams Control Board for Motor Operation.

A form of starter for motors and pumps over 20 H.P. is shown on Fig. 2. This is a recent patented production of the firm, and it is likely to meet with very wide success, owing to the fact that the starting of the motor is accurately and automatically performed, irrespective of the load conditions. The float switch (or even a tumbler switch) causes the main switch to close, but the cutting out of resistance in series with the motor armature is accomplished by separate magnetically operated contactor switches, the rate of acceleration being automatically "steadied" by current relays in the armature circuit. These have the effect, it is claimed, of always giving a correct starting period, and never under any circumstances draw an excessive current from the line or cause violent acceleration of the pump. Indeed, they may almost be said to act intelligently, for they protect the pump as well as the motor, and anyone who knows what it means to get a long column of water into motion without producing any surging or other effects, will undoubtedly appreciate the advantages of this apparatus.

An important application of "Igranic" controllers is to the automatic operation of fire pumps from a distance. On the discovery of the fire it is only necessary to press one of the fire buttons scattered about, say, a country house, to start the motor-driven pump and get a plentiful supply of water at a good head. Many such installations are to be found all over England, and though subjected to frequent surprise tests, they are claimed never to fail. Other applications have been to sewage pumps, pumps for hydraulic machinery, and even to pumps for spirituous liquors. The construction of Adams "Igranic" control gear is robust and strong, and can be absolutely relied on to give constant and efficient service. This question of control is undoubtedly very important, and where electrically-driven equipment is employed on such work as fire pump supply it is essential that every care should be taken to ensure the reliability of the equipment. This seems to be done in the "Igranic" switchgear.

Westinghouse Motors for Pumping Work.

AMONG the activities of the British Westinghouse Co. may justly be placed that of electrically-driven pumping plant. And it is not out of place that this should be so, for the driving of pumping plant is one of the most widespread uses of electric power in collieries and mines. The adaptability of the electric drive, and its immense advantages over any other form of power for this particular service, were generally acknowledged at a time when the manifold other uses of electric power in collieries were still under discussion. Whether the electric pumping sets are large or small, or whether they are far in-bye or at the shaft, they work with great efficiency and economy, and their general advantages are now well appreciated.

The pumping outfit shown in Fig. 1 has recently been installed underground at the Hebburn Colliery of the Wallsend & Hebburn Coal Co., near Newcastle. The motor, with its accompanying control gear, is of the British Westinghouse Co.'s standard design for this particular work; while the horizontal three-throw ram pump was built by Messrs. Frank Pearn & Co., of Manchester, and is capable of dealing with 600 gallons per minute at a head of 1,050 ft. The motor is of the three-phase induction type, with enclosed slip-ring. It is wound for 600 volts and develops 280 B.H.P. at 390 revs. per min. It is fitted with an extended shaft, rope pulley and out-board bearing. The motor needs practically no attention, and operates with high efficiency at all loads; the design being strong and substantial throughout. The control-box shown adjacent to the motor is provided with an oil-immersed combined main switch and circuit-breaker, to which the supply cables from the generating station are led, and an ammeter for showing the current passing; the conducting cables being taken into and out from the box through substantial insulating bushings let in the iron case. The controller, which may be seen at the extreme right of Fig. 1, is of the oil-immersed gas-tight drum type, and is fitted with special cable joint-boxes, which are bolted to lugs on the iron tank. It is connected between the control box and the motor, and consists principally of two intergeared drums, one of which controls the supply of current to the stator or stationery part of the motor, while the other varies the resistance in the rotor circuit, the number of steps being seven. The current-carrying parts are fitted with renewable arcing tips, which may be easily removed and replaced when necessary.

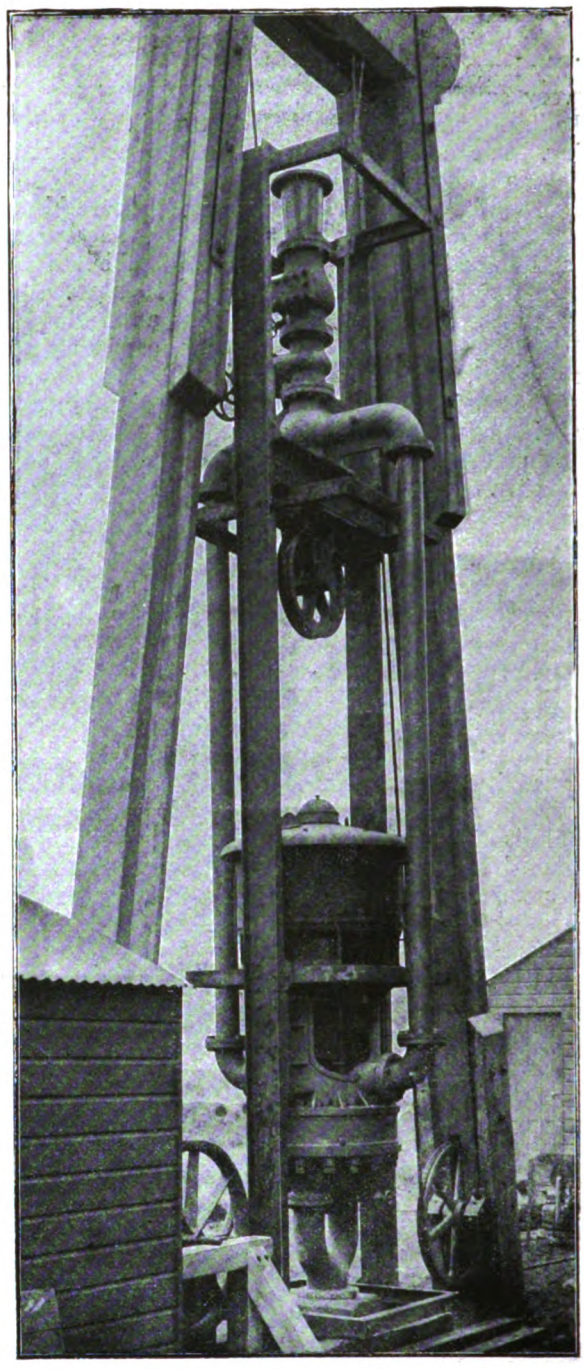

Fig. 2.—Westinghouse Pump at Tywarnhaile Mine.

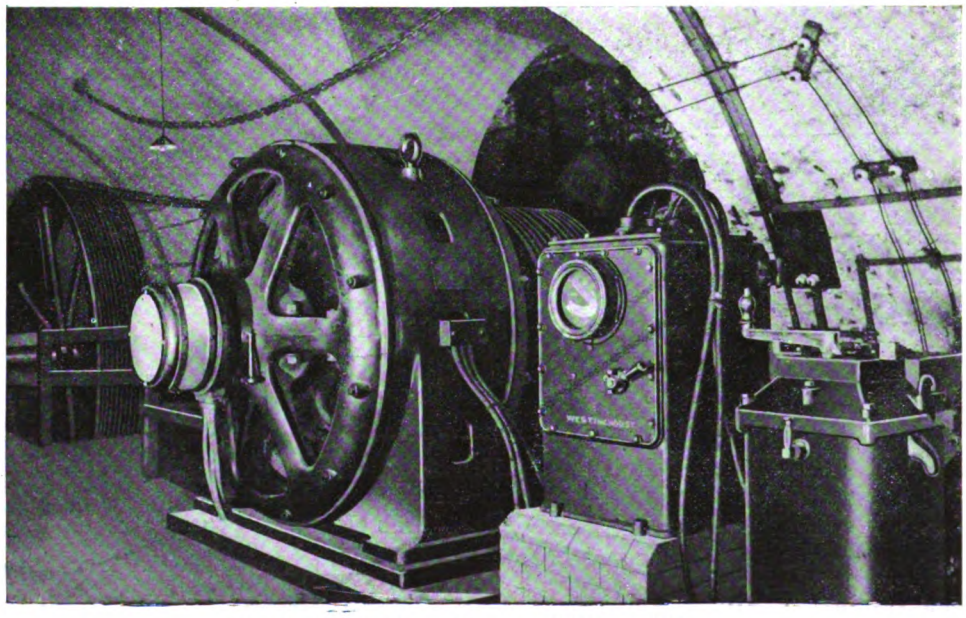

Fig 1.—Westinghouse Pump at Hebburn Colliery.

In connection with coaling work we may call attention to two Westinghouse three-phase squirrel-cage 3,000-volt motors, which are employed in operating centrifugal pumps for supplying water for coal washing. In this type of motor the rotor has no electrical connection with the outside circuit; and the connections to the fixed portion are made through a special water-tight connection box fixed on the side of the motor. The two control switch panels are placed near the set. The motors are of

Digitized by Google

125 and 50 B.H.P. respectively, and are coupled direct to the pump spindles. They are supplied at 3,000 volts, 50 periods, and run at 600 revs. per min. The smaller pump works intermittently (without suction) against a head of about 35ft. The larger pump works under suction from depths varying from 15 ft. to 30 ft., and delivers its water in two stages. The first stage is approximately 41 ft. above the centre of the pump, and 75 per cent. of the water is taken off here; the second stage is 14 ft. higher, or 55 ft. from the centre of the pump. The total quantity of water pumped is about 3,500 to 4,000 gallons per minute.

Another interesting type of electrically-driven pump is that shown in Fig. 2. This illustration shows a 100 H.P. alternating-current sinking pump at Tywarnhaile mine in Cornwall. These vertical motors, besides being compactly built, are of a design embodying the first-class performance, simple construction and hardy characteristics of the ordinary Westinghouse horizontal motors.

Problems of Electric Haulage.

THERE are certain industrial operations for which a motor seems eminently suited. To drive, say, a fan, requires that the driving agent should be capable of running for long periods under absolutely constant load, and such a condition is fulfilled, other things being the same, equally well by a steam engine as by a motor. But when we have to consider the question of driving plant whose operation gives a varying load, the problem is somewhat different. In the case of a hoist, for instance, the load rises almost momentarily from nothing to a maximum, and may drop again practically immediately to nothing, while these periods of activity are interspersed with intervals of doing nothing. The load which results is, therefore, by no means ideal, and what idealism there is is considerably reduced when steam driving is considered. There are always no-load losses, the acceleration is low and reversing difficult. As a set-off to this the motor is not expending energy when it is not actually working, it can be made to accelerate quickly and can be easily reversed.

It is, therefore, not surprising that electrically-worked hoists of large size are coming into extended use in shipyards, mines and factories generally. Unfortunately, in this country, progress has not been so great in this direction as abroad, though the favourable comments on the electric drive for this purpose in the report of the Royal Commission on Mines should not be without its effect on this state of things. On the Continent and in America more progress has been made, in the latter country especially in the shallow coal mine district.

The problems which have specially to be faced in dealing with such machines are mainly those pertaining to the great variability of the load and its effect on the motors themselves, and the operation of the line generally. Special precautions have to be taken to equalise the load as far as possible, to improve the load factor and to prevent dangerous surges on the line. The usual precautions attendant on the use of electricity in mines, such as fire-proofness and safety from shock, must, of course, also be taken.

The problem of equalising the load varies in complexity in haulages with the gradient up which the load is to be drawn. In a certain case in America, where the gradient varies between 5·0 and 8·5 per cent., a 500 H.P. compound motor is used controlled by semi-automatic magnetic gear. Line surging is practically eliminated by fixing a relay on the controller that prevents the starting switches from closing too rapidly. Another relay opens the circuit on overload, while, should the cars strike an obstruction, an arrangement is provided for bringing the motor automatically up to speed again. A very usual way of getting over the difficulty, especially in vertical, or nearly vertical, shafts, is to employ a balanced system in which the weight of the rising full cars is compensated, as far as possible, by the falling empty ones. There is, of course, besides all these ideas, the system of using a flywheel (a method which has been much before the public recently). This system has many advantages, almost its only disadvantage being the high first cost.

The more extended adoption of electrically-driven haulages in this country will follow as a necessary corollary of the general progress of the electric drive in mining work. It is a special subject, and must be specially considered, though there seems no good reason to believe that any problem of this type cannot be satisfactorily solved.

NOTES.

Restricted Hour Supply.

THE annual report of Mr. P. J. PRINGLE, electrical engineer to the Burton-upon-Trent Corporation, shows an unusual state of affairs. Notwithstanding that the output of units by the electricity department is practically the same as a year ago, and that the number of higher priced units sold shows a considerable decrease, the surplus declared on the year's working is nearly double that of last year, and is the highest shown for many years. This happy result has been brought about by a reduction of no less than 27·6 per cent. in the cost of fuel, due to important economies introduced in the boiler house. With these we are not for the moment concerned. It is interesting, though, perhaps, disappointing, to notice that the revenue from private lighting is actually less than it was seven years ago, although the lamp connections have increased by 47 per cent. during that time. More satisfactory progress, however, is recorded as regards power supply. In this connection it will be remembered that the Burton undertaking is one of the few in this country which have made a feature of restricted hour supply. The success attending this system at Burton is well known, and recent experience merely adds to the favourable impression previously held. Mr. PRINGLE mentions that 80 per cent. of the total horse-power connected and 79 per cent. of the total number of units sold for power are used on the restricted hour principle. This seems to indicate that the consumption of energy per horse-power installed is not appreciably diminished when the restricted-hour system is adopted. As Mr. PRINGLE also mentions that the cost of generating the restricted hour units is only about 35 per cent. of the revenue obtained, it is evident these units must have had a very important effect on the financial success of the undertaking during the last year or two. As Burton power users are now obtaining energy on the restricted hour system at an average price of 0·855d. per unit, the advantages of the system are by no means confined to the supply undertaking.

Electricity in Coal Mines.

APART from the interest aroused by the likelihood of amended regulations for the use of electricity in mines as a result of the forthcoming report of the Departmental Committee appointed by the Home Secretary a few months ago to investigate this question, much attention has recently been paid to the apparatus used in collieries. Considerable discussion has also taken place in connection with the Paper read last year by Mr. ROBERT NELSON, H.M. Electrical Inspector of Mines, before the Institution of Mining Engineers, his unqualified decision in favour of the three-phase system, and also his advocacy of armoured cables, being criticised. A very interesting discussion took place last week on a Paper by Mr. W. W. WOOD, read before the Institution of Electrical Engineers. This Paper was mainly concerned with the question as to whether it is desirable to earth the neutral point of a three-phase colliery installation; but the question of armouring is also intimately connected with this problem.

A SLIGHT misunderstanding appeared to arise during the discussion, due to some speakers, who confined their attention to the underground installation, criticising those who dealt with the question of transmission lines, the former speakers overlooking, perhaps, the fact that the author introduced the question of transmission lines into his Paper. In this connection it may be pointed out that

Digitized by Google

the question of an earthed neutral on a transmission line is different from that in the case of a mine.

At the present time efforts are concentrated on reducing any danger attending the use of electricity in collieries, and from that point of view the discussion has certainly proved valuable in bringing prominently forward the various features to be considered. It will be seen from our account of the discussion that opinion is by no means unanimously in favour of an earthed neutral or of armouring in all cases. Although, perhaps, an exception might be made in the case, mentioned by Mr. Wood, of a colliery where armouring is said to be destroyed in three weeks, due to the action of acids or salts, we think that a continuous earthed armouring is essential for cables used in mines. This system may possibly introduce a feeling of security not always justifiable, but with skilled attention—the necessity for which cannot be too strongly emphasised at the present moment—and the use of the protective apparatus now available, it should prove more satisfactory than running the risk of an arc or spark external to any cable, apart from the greater security against shock.

The Progress of Pure Science.

It is difficult for the engineer engaged in technical matters to follow at all adequately the continuous advance of pure science, and yet it is important that he should not lose sight of what is being done. Of course, he cannot well expect to keep in touch with the more abstruse branches, but an acquaintance with those subjects that may at any time become of practical importance is most desirable. It cannot be too fully borne in mind that advances in technical branches must largely be due to the utilisation, from time to time, of phenomena which have so far been regarded as of merely scientific interest. A case in point is the telephone relay of Mr. S. G. Brown, which is described in another column. The action of this instrument depends upon the electrical resistance of a minute spark-gap—a matter which has so far been passed over as of very little, if any, practical interest. Thus it behoves the engineer to keep his eyes open. It is with this object in view that we are starting in the present issue a series of articles by Mr. D. Owen on Recent Physical Research. Unfortunately, the pages of The Electrician are necessarily taken up too fully with technical matters for adequate attention to be paid to pure science. We hope, however, that these articles, which will appear at intervals, will to some extent serve to fill the gap and to keep our readers in touch with what is going on. The first article is on "Positive Electricity," and this will be followed by other contributions on subjects of rather greater practical importance than we can expect positive electricity to be for at least some time to come; though it must not be forgotten that the electron—so long associated with essentially pure science—is the starting point of Mr. Brown's relay, so that it behoves us to be guarded in our remarks.

"The Central."—The April number of this periodical contains articles ranging over engineering in general. They include "Main Drainage," by Mr. H. G. Lloyd; "American Hydro-Electric Development," by Dr. E. W. Marchant, and "Some Aspects of Chemical Engineering," by Mr. C. J. Guttmann. The issue is prefaced by a biographical notice and excellent photogravure of Mr. Wm. Duddell, F.R.S.

National Electrical Manufacturers' Association.—The Secretary (Mr. F. B. O. Hawes) informs us that he has received many communications with reference to the meeting which the Association is convening on 23rd inst. at Caxton Hall to consider the effect of Free Trade or Protection on the electrical industry, and we are asked to announce that admission will be by ticket, and that tickets will be sent by the Association to all its members, and to all the members, associate members and associates of the Institution of Electrical Engineers.

Electrical Mill Driving.—A new contract for electric power and lighting supply has this week been concluded between the Acme Mill Spinning Co., Pendlebury, and the Lancashire Electric Power Co. The contract came into operation on May 1st; it includes a portion of the Albion mill, which adjoins the Acme mill, and covers a long term of years. Considerable controversy has in past years been expended among electrical experts and mechanical engineering experts as to the entire suitability and economy of electric driving for large spinning concerns, and the settling of this contract may be regarded as an important declaration on the point. The Acme mills is one of the few large spinning mills in England without a chimney.

Personal.—The Salford Electricity Committee report that they have accepted, with very great regret, the resignation of Mr. V. A. H. M'Cowen of his position as electrical engineer to the Corporation. They have expressed their sympathy with him in the continued ill-health which has led to his resignation, and hope he may soon be restored to his usual health to enable him to continue a career which has been both honourable to himself and of benefit to the public. The Committee have further placed on record their high appreciation of the able and efficient manner in which Mr. M'Cowen has fulfilled his duties, and the sound advice he has always given the Committee, thereby rendering valuable service to the Corporation and the ratepayers generally.

Street Lighting in Paddington.—The employment of high candle-power metal filament lamps for street lighting is now receiving an interesting application in the Paddington district. The Metropolitan Electric Supply Co. have recently installed two 400 c.p. Osram lamps on an arc lamp standard in Westbourne-terrace, Paddington. The illumination is exceedingly good, and, in fact, seems greater than it really is, while the electric lamps are distinguishable both by their colour and greater brilliancy from quite a distance. The lamps themselves are mounted in fluted globes, and we understand that although these have been in use for a month it has not yet been necessary to clean them. Besides these lamps three gas pillars at the other end of the terrace, on the bridge crossing the Great Western Railway, have each been fitted with a 100 c.p. Osram lamp with similar satisfactory results.

A Thunderstorm Observatory.—It is announced that a thunderstorm observatory has been established in Spain by Señor G. J. de Guillen Garcia, in which atmospheric discharges, both local and distant, are detected graphically and acoustically. A wireless telegraph instrument is used for this purpose, because each lightning discharge is accompanied by electro magnetic waves similar to those used in wireless telegraphy. If there is a storm anywhere within a radius of 500 miles the observer is notified of the fact by the recording instrument. As all barometric depressions that pass over Western Europe come from the Atlantic Ocean, the new observatory gives meteorologists due warning of the approaching disturbance. By noting the intensity of the sounds produced in the receiver and observing whether they grow more distinct or less, it is possible to determine the approximate course of a storm.

The Tramways and Light Railways Association.—The "Official Circular" of this Association for April contains corrections and additions to the list of members published in the March issue, full particulars in regard to the Association's Congress to be held in Dublin on May 12th and 13th next, correspondence with the Board of Trade in regard to third party accidents, copies of two recent judgments given in regard to rating of tramroads and to lease of tramways respectively, and other matters concerning the affairs of the Association.

London, Brighton & South Coast Railway.—With reference to the statements published concerning the further electrification of the L.B. & S.C. Co.'s suburban line to the Crystal Palace, we are in a position to state that whatever the directors have decided will not be publicly stated until the next meeting of the shareholders, when particulars will be furnished by the chairman and the decision of the directors will be made known. It is correct to state that the subject is under serious consideration, but this was clearly indicated in the chairman's remarks to the shareholders at the last meeting.

National Physical Laboratory.—Vol. VI. of "Collected Researches" has been issued by the National Physical Laboratory, and contains the following reprints:—

"Repeated Impact Testing Machine at the National Physical Laboratory," by T. E. Stanton, D.Sc.

"The Resistance of Materials to Impact," by T. E. Stanton, D.Sc., and L. Bairstow, A.R.C.Sc.

"Report of the Experimental Tank Committee (1908)." Part I., by the Committee: part II., with an Appendix, by R. T. Glazebrook, M.A., D.Sc., F.R.S.

"On the Resistance of Thin Plates and Models in a Current of Water," by T. E. Stanton, D.Sc.

"An Apparatus for Measurements of the Defining Power of Objectives," by J. de Graaff Hunter, M.A.

"On the Measurement of Wave-length for High-frequency Electrical Oscillations," by A. Campbell, B.A.

"On Magnetic Testing of Iron with Alternating Current," by A. Campbell, B.A.

"On a Method of Testing Photographic Shutters," by A. Campbell, B.A., and T. Smith, B.A.

"Non-inductive Water-cooled Standard Resistances for Precision Alternating-current Measurements," by C. C. Paterson and E. H. Rayner, M.A.

"The Proposed International Unit of Candle-power," by C. C. Paterson.

"On the Insulation of Inductive Coils," by A. Campbell, B.A., and T. L. Eckersley, B.Sc.

"On Cadmium Amalgams and the Weston Normal Cell," by F. E. Smith, A.R.C.Sc.

"The Elastic Limits of Iron and Steel under Cyclical Variations of Stress," by L. Bairstow, A.R.C.Sc.

"The Crystalline Structure of Iron at High Temperatures," by W. Rosenhain, B.A., D.Sc., and J. C. W. Humfrey, B.A., M.Sc.

Operation of an Edison Accumulator Car.—The "Electric Railway Journal" gives some figures regarding the operation of an Edison accumulator car which has been running regularly on the road since March 3rd. The car leaves the barn at 6 a.m., with the batteries fully charged. It travels over the line continuously until 8:30 p.m., during which time it handles the regular traffic of the line in 14 round trips, covering a distance of 66·78 miles. At 8:30 p.m. the car comes into the car house, is inspected and charged for five hours. The average expenditure of energy at the motors is 529 watt-hours per car-mile, and at the 'bus bars, 853 watt-hours per car-mile. On March 28th and March 29th a test was made to determine the mileage capacity of the car when carrying a normal passenger load. The car made 85 miles and then was found to be practically discharged. On the last trip in the 85th mile run the car took on 27 passengers at the Twenty-third-street ferry making a total of 31 persons with the motorman, conductor and two engineers. The track conditions are bad and there are 46 curves in each round trip. On the long run of 85 miles there were approximately 700 stops. The designers of this car had obtained by April 1st a record of performance of the Edison battery covering a period of 476 charges and discharges in commercial service. At the end of this number of complete charges and discharges, the battery was found to be 11 per cent. higher in capacity than when at first put into service. Translated into car-miles, taking 80 miles per charge (5 miles less than was secured in the test run), the car travelled 38,800 miles and the battery appreciated in capacity 11 per cent. over its original rating.

Schilowsky Monorail.—A demonstration was given at the Westminster Palace Hotel on Wednesday last of a monorail system, which is the invention of His Excellency M. P. Schilowsky. The model locomotive exhibited was equipped for steam operation, and was shown running over a short length of monorail track. Equilibrium of the locomotive and cars or trucks is obtained by means of what is known as a "gyro-car," this being (in the case of the model) a truck fitted with a steam-driven gyroscope, and a special device by means of which the stability of the system is maintained. The gyroscope is mounted on a vertical axis in a frame which is pivoted, at points below the centre line of the flywheel, to the truck itself. The gyro-frame is therefore free to oscillate in a longitudinal direction about the pivot points. Any movement tending to oscillate the flywheel frame applies a restoring couple to the gyroscope, and through it to the truck, maintaining the latter in a horizontal plane, irrespective of unequal loading or shocks. This restoring movement is applied to the gyro-frame through the medium of a pendulum, which is coupled by rope or chain to a swinging quadrant. A portion of this quadrant is fitted with a rack and when the pendulum swings over sufficiently this rack is brought into engagement with a constantly rotating pinion, driven in the model by a small steam engine. The quadrant is also coupled by a rod with the gyro-frame. When the pinion engages with the quadrant a smart shock or push is given to the gyro-frame, and the leaning tendency of the car which initially moved the pendulum is corrected. The model shown remained satisfactorily in balance, and demonstrated the feasibility of the system on the scale shown. It is claimed for the system that slow moving gyroscopes will be possible, and that only one flywheel is needed. Fuller details of the method are promised shortly.

Wireless Control of Airships.—An interesting model airship of the lighter-than-air dirigible type is at present being shown by Mr. Raymond Phillips at the London Hippodrome. The balloon, which is cigar shaped, is 20 ft. long by 5 ft. in diameter, and carries a wooden frame work suspended below it for supporting the equipment. This consists of four propellers, two of which have vertical axes and are worked in parallel to give upward or downward motion as required, and the other two are placed astern for propulsion. The latter are carried at the two ends of a horizontal beam, which is free to swivel round in a horizontal plane. If one propeller alone is rotating it takes up a position near the "keel," and thus throws the model round rapidly, but when both propellers are running the movement is straight forward. No rudder is provided. The propellers are run electrically by electric motors supplied with current from a 4-volt battery of accumulators. The wireless part of the equipment is simple. Electric waves are produced by a coil and small antenna in the usual way. The waves are received by a couple of transverse rods and a coherer, which, by means of a relay, permit an electromagnet to be energised and to pull over a lever. This lever in turn pulls round a drum provided with a number of contacts, and at the same time the coherer is decohered at the end of each stroke of the lever by a tapper worked by an electromagnet. At each impulse the drum is drawn round to a fresh position, and therefore to a fresh contact, by a ratchet action. In this way any desired contact can be obtained by maintaining the impulses for a sufficient time; that is, any of the motors can be worked, or any circuit closed for which contacts have been provided. The model is interesting and works well. As to the use of such wireless methods in war, the inventor does not hold any strong views. He states that he has a device in mind for preventing interference. In actual warfare, however, he does not anticipate wireless control of a ship's movements, but rather that a definite course would be set at the start, and that explosives would be dropped by wireless means at the desired moment.

Digitized by Google

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. B. S. Cohen contributes some notes on a recent article by Dr. A. Ebeling dealing with "Aerial Telephone Lines on the Pupin System."

Mr. D. Owen contributes an article on "Positive Electricity."

Before the Institution of Electrical Engineers yesterday evening Mr. S. G. Brown described a Telephone Relay which he has devised, and which depends for its action upon the electrical resistance of a very small spark-gap.

We give an account of the discussion which followed the reading of Mr. W. W. Wood's Paper before the Institution of Electrical Engineers on "Earthed versus Insulated Neutrals in Colliery Installations."

Legal.—Lord Dundas has delivered an interesting judgment in the appeal of Glasgow Corporation against the assessment of their municipal tramways by the Assessor of Railways and Canals.

The Official Referee (Mr. Pollock) has given judgment in the action brought by the Electrical Co. *v.* O. H. Thomas, Son & Co. for the recovery of money due for electric mining plant supplied by plaintiffs. The hearing of the case occupied about 40 days and judgment has now been given for plaintiffs on the claim and counter-claim, with costs.

Directors' Reports.—The report of the Great Northern Telegraph Co. for 1909 is interesting reading. The chairman (Commodore E. Suenson) in his remarks to the shareholders, touched upon several items of international importance.

The operations of the British Westinghouse Co. for 1909 resulted in a further small debit balance (£798), after considerable sums had been allotted to depreciation.

"Trade depression" has seriously affected the Welsbach Incandescent Lamp Co., whose directors were compelled to pass the dividend on the ordinary shares, and have expressed the view that there is no hope under existing conditions, of any dividend on this class of share. A writing-down of the capital by the sum of £843,000 is advised.

INSTITUTIONS AND SOCIETIES.

University of Cambridge.—It is proposed to appoint the Vice-Chancellor, the Master of St. John's, the President of Queen's, Prof. Hobson, Dr. Darwin, Mr. R. St. J. Parry (Trinity), Mr. J. B. Lock (Caius), Mr. W. L. Mollison (Clare), Mr. W. H. Macaulay (King's), and Mr. H. McL. Innes (Trinity) a syndicate to consider the financial administration of the various scientific departments of the University and the financial relations between these departments and the Museums and Lecture Rooms Syndicate. The syndicate are to confer with the Financial Board, the General Board of Studies, the Museums and Lecture Rooms Syndicate, the heads of the various scientific departments, and such other bodies or persons as they may think fit, and to report to the Senate before the end of Lent Term, 1911.

Among the recipients of honorary degrees to be conferred this term will be: Principal Sir Oliver Lodge, F.R.S., and Prof. W. H. Perkin, F.R.S.

Faraday Society.—This Society gave their first dinner on Wednesday, April 27th, at the Trocadero Restaurant, in honour of Prof. P. Walden, of Riga, and Prof. Ph. Guye, of Geneva, who came to London for the purpose of taking part in a discussion on "The Constitution of Water," which took place on the previous evening. The President, Mr. James Swinburne, F.R.S., was in the chair, and there was a very good attendance of members and their friends. Among the guests present were Sir Joseph Larmor, Prof. H. B. Dixon, and Dr. C. Chree. After the loyal toasts had been honoured, Mr. W. R. Bousfield proposed the health of the guests of the evening, Profs. Walden and Guye, dwelling particularly on the variety and importance of their contributions to physical chemistry, and emphasising the value of such visits as those of Profs. Walden and Guye to London in promoting a spirit of international friendship. Prof. Walden, who spoke first in English and subsequently in German, referred to the scientific relationship between Russia and Great Britain, remarking incidentally that the first Russian chemist was an Englishman, sent by Queen Elizabeth to Russia in the sixteenth century. Comparing the intercourse of men of science with physical reactions, with which his hearers would all be familiar, he remarked on the important part "association" and "dissociation" played in such intercourse and on the benefits to science resulting therefrom. Prof. Guye, who responded to the toast in French, dwelt on the debt which chemists all over the world owed to Faraday, and he gave an interesting account of Faraday's visit to Geneva when he accompanied Sir Humphrey Davy on his tour through Europe.

The health of the other guests was proposed by Mr. Bertram Blount, and Sir William Ramsay and Sir William Tilden responded. Dr. T. M. Lowry proposed the toast of "Kindred Societies," coupling with this the names of Sir Joseph Larmor, secretary of the Royal Society, Prof. H. B. Dixon, president of the Chemical Society, (which Dr. Lowry described as the "mother" of the Faraday Society), and Dr. Charles Chree, past-president of the Physical Society, (which he claimed might fairly be called the "father" of the Faraday Society), while the Institution of Electrical Engineers might be regarded as the "generous uncle," seeing that 48 out of the 50 meetings which had been held by the Society took place in the library of the Institution. To this toast Prof. H. B. Dixon responded.

In conclusion, Dr. C. Chree proposed the toast of the Faraday Society, coupled with the name of the president, Mr. James Swinburne, who, in his reply, dwelt on the work which the Society was doing in covering gaps in the borderlands of physics and chemistry, both on the theoretical and technical sides, which were not covered by existing societies.

Institution of Civil Engineers.—The council of this Institution have awarded a Telford premium to Messrs. J. Dalziel and J. Sayers for their Paper on "The Single-Phase Electrification of the Heysham, Morecambe and Lancaster Branch of the Midland Railway."

Birmingham Section of the Institution of Electrical Engineers.—The list of names which will be submitted at the Annual General Meeting on May 25, for election on the committee of this Section, is as follows: *Past Chairmen*, Messrs. R. A. Chattock, R. K. Morcom, and Prof. G. Kapp. *Chairman*, Mr. M. Railing. *Vice-Chairman*, Mr. A. M. Taylor. *Committee*, Messrs. J. H. Barker, W. C. Goodchild, J. P. Kemp, M. Kloss, W. J. Larke, F. M. Lea, J. F. Lister, F. J. Moffett, D. K. Morris, C. E. C. Shawfield, W. E. Sumpner and R. Threlfall. *Hon. Secretary*, Mr. H. B. Matthews.

Yorkshire Section of the Institution of Electrical Engineers.—At the Annual General Meeting of this Section the following were elected as officers for the Session, 1910-11:—*Chairman*, Mr. T. Harding Churton. *Vice-Chairman*, Mr. Wilson Hartnell. *Committee*, Messrs. J. D. Bailie, E. A. Barker, A. J. Cridge, W. Emmott, J. W. Hame, A. B. Mountain, S. D. Schofield, J. McFall Smyth, G. Wilkinson, W. B. Woodhouse, H. H. Wright and Dr. R. Pohl.

ARRANGEMENTS FOR THE WEEK.

SATURDAY, May 7th.

Birmingham and District Electric Club.

7 p.m. Meeting at the Colonnade Hotel, New-street. Paper on "The South Staffordshire Mond Gas Distributing Plant," by Mr. Wm. Dudley.

WEDNESDAY, May 11th.

Junior Institution of Engineers.

7:30 p.m. Meeting at the Royal United Service Institution, Whitehall. Paper on "Notes on the Running of an Electricity Works," by Mr. L. H. Jockel.

THURSDAY, May 12th.

The Institution of Electrical Engineers.

8 p.m. Meeting at the Royal Society of Arts, John-street, Adelphi, W.C. Paper on "Street Lighting by Modern Electric Lamps," by Mr. H. T. Harrison.

FRIDAY, May 13th.

Royal Institution.

9 p.m. Meeting at Albemarle-street, Piccadilly, W. Discourse on "Radioactivity as a Kinetic Theory of a Fourth State of Matter," by Prof. W. H. Bragg, F.R.S.

Tramway and Light Railways Association.

THURSDAY and FRIDAY, May 12th and 13th.

Meeting at Dublin.

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. B. Crompton, C.B.

The following orders have been issued for the current week:—

Monday, May 9th, "A" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 9:30 p.m.

Tuesday, May 10th, "B" Company.—Company Drill, 7 to 9:30 p.m.

Wednesday, May 11th.—Gymnasium, 6 to 9:30 p.m.

Thursday, May 12th, "C" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 8 p.m. Technical Drill, 8:45 to 9:45 p.m.

Friday, May 13th, "D" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 8:30 p.m. Technical Drill, 8:45 to 9:45 p.m.

DEVELOPMENT IN THE PRODUCTION OF ELECTRIC POWER.*

ITS APPLICATION AND BEARING UPON THE IRON AND STEEL INDUSTRIES.

BY D. SELBY BIGGE.

Summary.—The author discusses recent developments in cheapening the cost of production of electric power, particularly in connection with the iron and steel industries. Exhaust and mixed-pressure turbines are referred to in this connection and the various types described, together with particulars of the saving to be expected. He next passes on to gas engines, and the use of blast furnace or coke-oven gas, and finally refers to electric rolling mills and electric furnaces. He points out that this country is suffering from lack of enterprise.

It has been the author's privilege to lay before the members of this Institute, from time to time, records of the various developments which have occurred in connection with electric power for industrial purposes. The progress made in this country during the past three years has been rather of the slow but sure order, and has not in any way been able to keep pace with the extraordinary enterprise and activity of the American and Continental manufacturers and engineers. It must be remembered that the author is confining himself, in remarks such as the above, to matters restricted to "electric power" and is not in any way referring to other industries. The acute depression of trade in this country during the past two years may have had a bearing upon the slow rate of progress made, but many opportunities have been lost during this slack period of bringing old works with obsolete methods up to date, and in making due preparations for working upon the bed-rock of economy when better times should set in. In this latter respect it must be realised that this country is to a large extent being outstripped by our American and continental competitors. Progress, therefore, and economy in productive methods are amongst the most important factors, if not the most important, in our being able to combat successfully the ever-growing competition with our home trade.

Coming now to the actual subject matter of this Paper, considerable progress has been made in the cost at which electricity can now be produced in iron and steel works having at their disposal waste gas, waste heat, and waste steam. One of the means by which this low cost of production has been attained has been brought about during the past three years by the advent of the mixed pressure turbine. As this is a subject to which the majority of iron and steel works, with their accessory sources of coal, coke, and iron-stone, are paying considerable attention at the present time, the author devotes some space to its consideration.

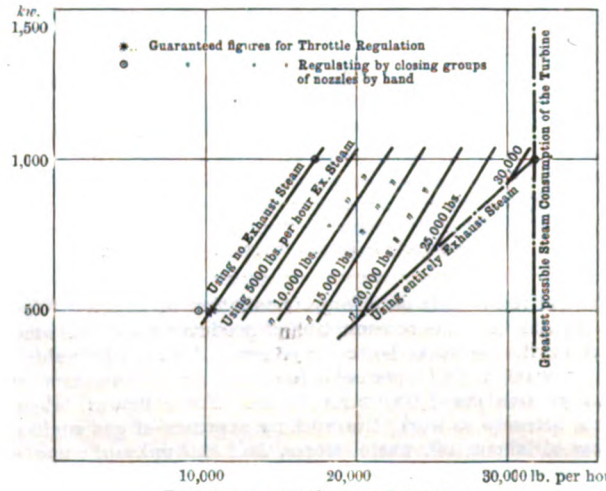
Mixed Pressure Turbines.—Whereas the purely exhaust type of steam turbine lends itself readily to those applications where a constant supply of exhaust steam is available, such as in the case of the exhaust from blast-furnace blowing engines, fans, pumping engines, &c., yet a want has been felt for a type of machine which could be relied upon to take full advantage of the steam available from engines working only intermittently. The latter condition is far more frequently met with in actual practice than the former, and the exhaust steam can now be fully utilised from intermittently working machines, such as winding engines, rolling mill engines, heavy punches and shears, compressors, steam hammers, and hoist engines. The exhaust steam recovered from such engines is conducted through pipes into a regenerative or heat accumulator, which in its turn feeds the turbine with steam at low pressure.

The action of a regenerative accumulator, taking water as the means of storing heat, is as follows:—The exhaust steam is taken from the engine, or engines, and mixed with the water until they become of the same temperature. Assume that a pressure of 1½ lb. to 2 lb. is allowed to take place in the accumulator. Directly the pressure drops, owing to the supply of exhaust steam being cut off, the water in the accumulator at once gives off vapour. If a vacuum is allowed to take place in the accumulator, further useful effect can be obtained. A valve should be fixed between the engines supplying exhaust steam and the accumulator, so that a vacuum cannot be carried further than the accumulator itself. The size and capacity of the apparatus is determined by the length of pauses which are required to be bridged.

The principles involved in the mixed pressure type of turbine are as follows:—The turbine is built in stages or impulse wheels, one set being designed and arranged for the working pressure of the existing boilers, and so constructed as to give off the full output of the turbine upon live steam when required, the other set being designed for the utilisation of exhaust or low-pressure steam received from the accumulator in the case of engines working intermittently, or direct from the exhaust of the engines running continuously. The low-pressure end of the turbine is also designed to give out the full rating or output upon low-pressure steam alone. The third condition is that in which, if the full supply of exhaust steam fails from any cause, live steam is automatically admitted to make up the temporary deficiency in the exhaust steam available. An important feature is that the high-pressure steam is admitted, when required, to the high-pressure stage without the intervention of a reducing valve, and thus the maximum efficiency is obtained from such high-pressure steam as may be used, to practically the same degree as in an ordinary high-pressure turbine. The governing and regulating arrangements by which this end is attained are absolutely automatic.

Not only can the mixed-pressure turbine be advantageously used in connection with rolling mill engines, winding engines, and other engines of the same category working intermittently, which do not possess, by the nature of the work they have to perform, the very high efficiency and steam consumption of cotton mill engines and triple expansion marine engines, but it has even been found possible to make use of exhaust turbines in connection with engines of the highest class alluded to above. It will be seen, therefore, that the field for the application of this system of power recovery is almost unlimited.

The author showed three diagrams illustrating the power recoverable in the shape of exhaust steam from three different types of engines. In the case of the simple engine it may be safely assumed, after making ample allowance for all losses, that in actual practice at least as much power can be obtained from the exhaust steam of such an engine as is obtained from the high-pressure steam in the cylinder. There are many engines in iron and steel works, and other kindred industries, to which this will apply. By converting such an engine into a condensing engine a comparatively small advantage will be gained, and so long as the engine is powerful enough for the work it has to perform it will undoubtedly pay to leave it as it is and utilise the exhaust steam in a low-pressure turbine combined with a condenser providing a high vacuum. The amount of power to be recovered in the case of a compound condensing engine amounts to 60 per cent. approximately. The third diagram showed that even in a triple-expansion high-pressure engine a considerable amount of power still remains to be recovered, but it might be found in works practice that it was not commercially advisable to make any alteration. In marine practice, however, there are undoubtedly possibilities of utilising the power lost. In order to obtain a high vacuum, first cost and power required to work the condensing plant should be carefully considered to avoid unnecessary expenditure in proportion to the results obtained.



Boiler press. 163·5 lb. per sq. in. Superheat 117° F. Exhaust steam 15·7 lb. per sq. in. abs. Cooling water 59 F. Revs. per min. 3,000.

STEAM CONSUMPTIONS OF A 1,000KW. (50 ∼) MIXED PRESSURE TURBINE.

The diagram herewith is of special interest as showing the actual steam consumption of a mixed-pressure turbine developing full load when supplied either partially or wholly with exhaust steam. The steam consumption is also shown for the turbine when using high-pressure steam only.

Cooling Plant.—With either the purely high-pressure, mixed-pressure, or exhaust type of steam turbines, it is essential that condensing plant should be installed. The three forms of cooling plant most commonly met with are the natural draught cooling tower, the open type cooling tower, and spray nozzles distributed over a pond. In this country the circulating water can be reduced to 80°F. or 85°F., ordinarily with natural draught cooling tower, or to 75 deg. with open-type cooling tower, which, however, occupies more space. Where ground space is not of great importance.

* Abstract of a Paper read before the Iron and Steel Institute.

Digitized by Google

and especially in open situations, spray nozzles are to be recommended as excellent results are obtained by their use, and if properly installed it is quite easy to maintain the temperature of the circulating water at the prevailing atmospheric temperature.

The following figures may be of interest :—If we take two mixed-pressure turbine units, each of 600 kw. capacity, working on exhaust steam only, and exhausting into condensers of the multi-jet ejector type, it would be found that about 220,000 gallons of water would be circulated per hour in order to maintain a vacuum of 27½ in. with barometer at 30 in. The area of pond required for the spray nozzle cooling plant for the above quantity of water would be approximately 7,800 sq. ft.,—*i.e.*, a pond 130 ft. long by 60 ft. wide. The two 600 kw. units referred to above, when working together on exhaust steam only, would require a total of approximately 48,000 lb. of steam per hour, and it would be found in practice that this steam being collected and used in the turbine, and circulated through the condenser to the cooling pond, would result in approximately 10 per cent. of the 48,000 lb. of water fed into the boilers being saved. Therefore a generating station with a plant of the type described is really in a better position from a boiler feed point of view than it was when its various reciprocating engines were exhausting to atmosphere.

Having reviewed the general principles involved in the use of mixed-pressure turbine plant, the author gives a brief description of the salient points of some of the distinctive types. The following turbines are described and illustrated in this connection : Parsons, Rateau, Curtis, Bergmann, de Laval, Zoelly and Westinghouse.

Gas Engines.—As showing the recent improvements in gas engines, the author describes the Mather & Platt, Nürnberg and Cockerill-Westgarth engines. It is mentioned that a furnace producing 250 tons of iron per day delivers enough gas to generate 10,000 B.H.P., of which 2,500 B.H.P. are required for the furnace equipment, leaving 7,500 B.H.P. for electric generating or other purposes. The following figures are given as running costs of Nürnberg gas engines :—

Four-cycle Tandem Double Acting.

1,200 kw.	0·0359d.	per kw.-hour.
900 kw.	0·0452d.	„ „
300 kw.	0·1164d.	„ „

Four-cycle Single-cylinder Single Acting.

300 kw.	0·165d.	„ „

Careful tests made on a large installation of Cockerill-Westgarth gas engines show the consumption of producer gas at full load to be 65 cubic ft. per brake-horse-power-hour, the calorific value of the gas being 146 B.Th.U. per cubic foot, and the oil consumption to be 0·275 gallons per 1,000 B.H.P.-hours. From figures taken from plants actually at work, the working expenses of gas engines, consisting of labour, oil, waste, stores, &c., and upkeep, come out at approximately 0·045d. per kilowatt-hour, this being for units of about 1,000 kw. size.

Cost of Production.—In the case of small and separate high-pressure installations, with reciprocating engines, obtaining their steam from coal-fired boilers, and of a capacity of, say, from 300 to 500 kw., a very usual figure of cost of production, with interest and depreciation included, is 0·6d. to 1d. per unit, the actual figure varying with the local conditions and the price of boiler coal. In many cases, especially those ranging between 100 kw. and 400 kw., it may be found desirable to purchase current from a public supply in preference to generating current oneself, if no waste assets are available. When, however, it becomes a question of providing current for the complete electrification of a large works, or for the driving of rolling mills and heavy machinery, the operating of electric furnaces and other applications demanding a large amount of current, then the question of cost of production at once becomes a vital matter, and the fullest advantage should be taken of any waste assets either in the form of waste heat, gas, or exhaust steam, which may be to hand. The power which may be required for schemes such as the above will be found to be anything between 1,000 kw. and 10,000 kw.

An interesting case of the application of mixed-pressure turbines for the economical production of power is the electrification scheme recently carried out by the Fife Coal Co. in connection with their collieries in Scotland. The principle adopted has been to lay down mixed-pressure turbines at those collieries where the greatest amount of exhaust steam might be available, and feed the power thus generated into a common network of mains, from which power could be drawn off to supply the requirements of their other collieries in the district. The Fife Coal Co. possess five mixed-pressure turbines, each of 1,000 B.H.P., and one of 800 B.H.P. Current is generated at 3,000 volts, 50 cycles. It is yet too early to gauge the total savings resulting from this comprehensive electrification scheme, but at one of the collieries, where a 750 kw. plant has been in operation for a year, the cost of production, after allowing 12 per cent. interest and depreciation upon the capital outlay, including a complete standby unit, and including wages, oil, stores, waste, &c., and an allowance for live steam, amounts to 0·2109d. per unit, made up as follows :—

Interest and depreciation (12 per cent.) upon £9,400.....	£1,128
Station attendants	160
Stores, oil, &c.	45
Coal for live steam and firemen's wages	684
	£2,017

The output is 2,295,000 units, so that the cost of production works out as 0·2109d. per unit. At this particular colliery the net saving which has been actually effected already exceeds £3,000 per annum, but as the plant is not yet fully loaded up and more motors have to be added, the ultimate saving will be considerably increased.

Electric Rolling Mills.—It is now three years since the author read a Paper before this Institute on this subject. With the exception of a certain number of continuous rotation mills, very slow progress has been made in this country in the development of reversing mills of high power. Amongst the pioneers in this direction have been Messrs. Dorman, Long & Co., of Middlesbrough, who were, with Messrs. Bell Bros., amongst the first in this country to adopt electric driving in their works. Messrs. Alfred Hickman, of Bilston, have also been amongst the first, and latterly the Skinningrove Iron Co. have adopted the electric reversing mill. Owing to the cheapening of the cost of production of electric current, many iron and steel works are now seriously considering the possibility of electric mills.

To give some idea of the comparative progress made on the Continent and in this country during the past three years, the author has been informed that one firm of electrical manufacturers alone has laid down 300,000 B.H.P. of electrically-driven mills on the Continent, and 20,000 B.H.P. in Great Britain. This applies to both reversing and continuous running mills. Another large firm have laid down on the Continent 234 mills with a total output of 305,000 B.H.P., so that it will be seen that two firms alone have laid down during the past three or four years on the Continent 605,000 B.H.P. in this direction.

Electrical Furnaces.—Reference is made by the author to the Héroult furnace and to electric induction furnaces. In a 5-ton furnace of the former type, using cold scrap, 700 kw.-hours are necessary to produce 1 ton of finished steel ; this is reduced to 140 or 160 kw.-hours when the metal is charged in a molten state. Electric induction furnaces are divided into two distinct types, the "simple induction" furnace, and the "combination" furnace. The "combination" furnace has the advantage over the "simple induction" type, that it is an efficient refining furnace. The power consumed varies in direct proportion to the degree of refining considered desirable.

General Applications.—In addition to driving by motors practically the whole of the auxiliary plant appertaining to an iron and steel works, there are many subsidiary purposes to which electricity can now be applied, such as shunting and works locomotives, transporters, charging machines, lifting magnets, &c. Improvements have been effected by the introduction of slow-speed motors, eliminating gearing. Three-phase motors have been brought into general use for cranes, live rolls, and other work where formerly continuous-current machines only were available. Variable speed motors have been built for work requiring a wide range of speed which was previously obtained by change gears or other mechanical devices. It would, in fact, be hard to mention any item of machinery and plant in an iron or steel works which cannot now be advantageously driven electrically.

After referring to the use of transmission lines and the higher voltages now employed with safety, the author sums up as follows :—

After frequent visits abroad, and by means of keeping constantly in touch with the improvements and developments taking place in other countries, the author is forced to the conclusion that what we are primarily suffering from in this country is apathy, and frequently lack of enterprise. The economic conditions in some of our older works are deplorable, and are not to be encountered in the countries of our ever-increasing competitors. If we are to continue to hold our own as a great productive nation, greater enterprise will have to be exhibited, and closer attention paid to the rapid improvements which are being so constantly effected by our competitors in their productive methods. When the absolute necessity for keeping abreast of the times is fully realised, there is no country in the world better able to meet successfully the growing competition than our own. There is now every indication that in the iron and steel industries at any rate, far greater attention is being given to schemes whereby economies in cost of production can be effected, and this is a welcome sign.

NEW METHODS OF TRANSMISSION EMPLOYED IN WIRELESS TELEGRAPHY.*

BY G. FERRIÉ.

Summary.—A brief review is given of the various methods that have been tried to obtain security in wireless telegraphy. A simple wave meter due to the author is described, and the calculation of damping is considered.

Among the numerous defects which were debited against wireless telegraphy on its first appearance the chief was that little security was offered as regards the messages entrusted to it; the reception of radio-telegrams could be spoilt, not only by the signals simultaneously sent from other stations, but also by the electric phenomena of the atmosphere. Although the numerous investigations which have been made with a view to remedying this state of affairs do not yet permit of absolute security for Hertzian messages, important improvements have been realised, and the situation is distinctly ameliorated. It is proposed to review briefly the various methods which have been tried, especial attention being given to those which have given the best results as regards the transmission.

The maximum of security would be obtained were it possible to realise, on the one hand, an emission of very regular unifrequent waves, having as small damping as possible, and, on the other hand, receiving and detector circuits of small damping, and which could only be set into vibration under the influence of an oscillatory movement of single, well-determined frequency. At the sender the desired result will be realisable when it becomes possible to generate sustained oscillations of sufficient power.

Since 1903, following Poulsen, numerous attempts have been made to utilise the singing arc supplied at low tension, with a view to producing such waves, but the results are not good enough for modern practice. The production of very high-frequency alternators for use in supplying the antenna directly without the intermediary of arc or spark is occupying attention in France at the present time, and the results obtained in this direction will shortly be published.

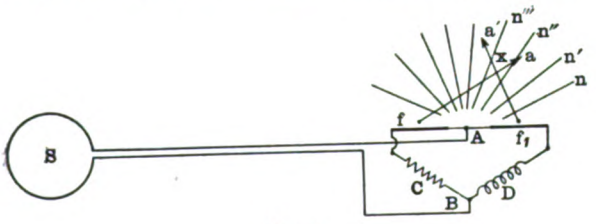

FIG. 1.

In the methods in actual use which employ the discharge of a condenser for generating the Hertz waves, either inductive or direct excitation is used. Wien has shown that the disposable energy is split up between the two vibratory motions whose wave-lengths differ the more the closer the coupling employed. It is, therefore, important to try to reduce the difference—that is, the coupling—at the same time keeping the value of the latter sufficiently high for the energy transference from the one circuit to the other to take place. It has been found that for values of the coefficient of coupling lying between 0·06 and 0·12 the energy is practically confined to a single one of those two oscillations, the slower or the faster, according to the relative values of the elements of the circuits. For the measurement of the coupling and the damping recourse is usually had to wave-meters and to the equations of Bjerknes.

Although there are many kinds of wave-meter, a new type has recently been devised by the author, which enables measurements to be made without any adjustments from a simple reading. The principle is as follows: Between two points, A and B (see Fig. 1), a certain effective E.M.F. (V) is maintained by means of a single loop, S, which encloses a part of the flux to be measured. Between A and B two circuits, *f*C and *f*D, are connected, each containing one wire (*f* and f_1) of a hot-wire ammeter and an impedance (C and D). Each of the wires *f*, f_1 controls a pointer (*a* and *a'*); these pointers are both capable of movement across the same scale. The currents which flow through each of the wires are given with sufficient approximation, for the case of damped waves, by the formula

$$I = V/(R^2+\omega^2L^2)^{\frac{1}{2}}; \quad I_1 = V/(R_1^2+\omega^2L_1^2)^{\frac{1}{2}},$$

whence $I/I_1 = f(\omega)$. For each value of ω the pointers cross at some point on a curve which can be empirically marked on the scale. The apparatus having been previously graduated, the measurement of the wave-length or frequency of an oscillating circuit is made by simply taking a reading of the point of intersection while the loop S is held near to the circuit.

For measuring damping the author has tried to apply the Bjerknes method directly, without plotting the curves, starting simply from the equation

$$Y\alpha_1\alpha_2(\alpha_1+\alpha_2) = E^2/16L^2 \quad . \quad . \quad . \quad (1); \quad \alpha_2 = R/2L,$$

whence $Y\alpha_1 R(2\alpha_1 L+R) = E^2/4$. Y is the maximum ordinate. A first measurement, giving R a certain value, allows of the determination of $Y(I^2)$ corresponding to resonance. Giving R, then, another value, Y′ is measured

$$Y'\alpha_1 R'(2\alpha_1 L+R') = E^2/4.$$

E being constant, the position of the circuits unaltered, and all the other elements known, it is possible to calculate $\alpha_1 L$ by means of these two equations. In using this method, in spite of every precaution, taking into account the skin effect and eliminating as far as possible all disturbing causes, it frequently happens that the values found are inacceptable, the calculated values being in some cases even negative. There are thus certain cases where is it incorrect to apply Bjerknes' equation in this manner.

The same anomalies are noticeable if the calculation is made by means of the maximum and a near point on the resonance curve, and also by the method indicated by Bethenod ("Lumiere Electrique," Vol. VIII., p. 301, 1909). These results may possibly be explained by the fact that the Bjerknes equations were established on the supposition that the discharge of the condenser in the circuit was complete, which is not always, if ever, the case.

The calculation of the damping of antennæ is not such a simple matter, owing to the apparent resistance due to radiation (radiation damping) and to the difficulty of measuring the low resistances of earth connections. It is, further, important in practice to keep down the ohmic resistance of the circuits. In the installations erected by the military telegraphs, and which are used chiefly by the War and Navy Departments, direct excitation is employed, and the resistance of the connections from the exciting circuit is reduced as much as possible, these being made of wide strips of thin sheet copper. Bethenod's formula for the high-frequency resistance of conductors shows particularly that it is important to diminish $2h$, the thickness of the sheet. Finally, the mass of the sparking electrodes has been made considerable, with a view to avoiding overheating during prolonged working.

This construction of the circuits has rendered it possible to make the capacity greater, other things being equal, and, as a result, increased the power brought into play, with loose coupling and reduced damping. Poincaré has shown that the radiation decrement of an antenna composed of several wires increases with the number of wires and with decrease of the mutual induction between the wires, hence with increase of the distance apart of the wires; but since the volume which can be given up to an aerial in space is limited in practice, it is advisable to employ a sufficiently large number of wires, within limits.

The method of charging up the condensers is also of importance, not merely as regards the quality of the spark, but also as regards ease of reception of the transmitted signals. Telephonic reception having been almost exclusively employed of late years, the number of sparks and the kind of sound they produce are both of some importance. The majority of installations at present employ low-frequency alternating current which is stepped up for charging the condensers by means of resonance transformers. With such transformers liberally designed, both as regards the iron and the copper circuits, it is easy to obtain pressure rises of 6 and even of 10. The number of sparks is not equal to the number of alternations, and it is possible, by suitable means, to vary the number of sparks between 10 and 20 on alternating current of 40 or 50 cycles per second. The sparks being so few in number, each represents a considerable power. Arcing is, however, not so persistent, since the sparks are due to pressure rises; but still, in order to avoid formation of an arc, the electrodes of the spark-gap have been made in the form of large parallel cylinders; for very large powers these cylinders should be kept rotating. A more musical note is obtained by using a metal wheel provided with teeth and rotating between the electrodes of the spark-gap. This suffices for 1 kw. to 2 kw., but if a larger amount of power is employed the heating is too great and arrangements must be made to ensure that the spark always jumps from the moving tooth to a new spot on the fixed electrode. For powers of 6 kw. to 10 kw. the author, with Fracque and Brenot, has obtained good results using a discharger arranged in the following manner: On a circular copper cylinder 25 cm. in length copper rods are fixed radially, each passing perpendicularly through the axis of the cylinder (*see* Fig. 2), and being equally spaced angularly; 15 or 20 such rods are used. The cylinder is driven by an electric motor, the minimum tangential velocity of the ends of the rods being 50 metres per second. The sparks occur along the length of the fixed elec-

trodes *ee* as each rod on the cylinder arrives in turn at the position where the air-gap is smallest.

A well-sustained musical note is obtained with this device, although some irregularity is caused by the blank spaces which occur in the series of sparks, and which are unavoidable when low-frequency alternating current of 42 or 50 cycles is used. A somewhat similar discharger has been installed at the Sainte Marie wireless telegraph station by Petit, the engineer of the telegraphs department. The use of such dischargers is, however, not limited to the case of alternating currents, for Marconi has for several years past been using a rotating disc discharger with direct current at 10,000 volts.

Instead of employing low-frequency alternating currents, it is advantageous to use alternating current of higher frequency—300 to 1,000 cycles per second—so as to be able directly to obtain sparks of the required frequency for a musical note. Such arrangements have, in fact, been employed by von Lepel and by the Telefunken Co. Investigations along this line have also been made by the author with Fracque and Brenot. These have shown that it is impossible to obtain a musical note with the ordinary discharger, since the blank spaces occur just as with low-frequency alternating current. If, however, the discharger is made in the form of a point opposed to a disc, a good musical note is obtainable; the better the longer the spark, which has been used up to 15 mm. These experiments were made using special alternators furnishing current of 1,000 and of 400 cycles per second. With the latter the note *g'* (about 400 vibrations) can be obtained, and by diminishing the excitation *c'*, and even *g*. These experiments have as yet, however, only been made with reduced power.

As regards the reception, the use of slightly damped waves has rendered it necessary to find new detectors. These are now available in the shape of detectors operating in virtue of their unilateral properties or as solid electrolytic cells.

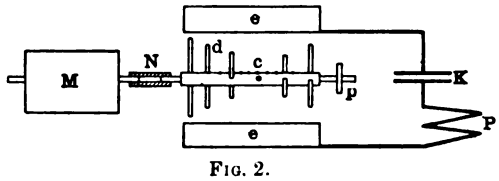

FIG. 2.

For still further safeguarding the receiver against disturbances caused by signals which are not intended for it, directive antennæ have been tried, with which a maximum intensity is obtained in a definite direction. One ingenious solution of this problem is that due to Bellini and Tosi, and this is being put into practical operation at Boulogne.

In conclusion, in spite of the inconveniences which radio-telegraphy still suffers from, but which may be expected shortly to be eliminated, the method finds every day new applications to the requirements of navigation, in the colonies and for home defence.

As an example, during the campaign in Morocco (January-September, 1908) all the official despatches of the expedition were transmitted from Morocco to Paris, or vice versa, by wireless telegraphy; from the interior to Casablanca by the field stations in communication with the "Kleber," and from Casablanca to Paris and inversely by the "Kleber" and the Eiffel Tower, the traffic reaching 3,000 words per day for the telegrams of the Ministry of War alone.

ELECTRICALLY DRIVEN REVERSING ROLLING MILLS.

At a meeting of the Institution of Engineers and Shipbuilders in Scotland some time ago, in connection with a Paper on this subject by Mr. C. A. Ablett, an important contribution to the discussion was made by Mr. T. B. Mackenzie. In view of the interest taken in this question at the present time we are pleased to be able to give the following account of Mr. Mackenzie's remarks:—

Since the first electrically driven reversing rolling mill was laid down at the Hildegardehütte Works, in Austrian Silesia, the matter has been very much in the minds of steel makers and their engineers, and has been the subject of several Papers, two at least of which have been by Mr. Ablett himself, and of a third he was the joint author. As I was one of a party of engineers and steelwork managers who visited the Hildegardehütte Works and saw the mill at work, it may be of interest if I put on record the leading particulars of the drive which was applied to a bar mill having four stand of housings, the rolls being 29½ in. diameter. The mill was originally driven by a twin reversing engine of the usual type, having steam cylinders 47¼ in. diameter, with a piston stroke of 49¼ in., the steam pressure being 90 lb. per square inch. On a vacant piece of ground beyond the engine was erected the electrical equipment, which consisted of three direct-current motors in series mounted on a shaft which was connected by an intermediate length with the mill. These motors had a normal capacity of 3,600 H.P., and a maximum of 10,350 H.P., and were capable of running up to a speed of 120 revs. per min. in either direction. The flywheel converter set consisted of a three-phase motor in the centre, of 1,500 kw. normal rating and 4,300 kw. maximum, operating on a 3,000-volt circuit with a frequency of 50 cycles. On each side of this motor was placed a flywheel 13 ft. in diameter, weighing 26 tons, and beyond this again the two variable voltage generators in series, each of 1,500 kw. normal and 4,300 kw. maximum rating, the E.M.F. of each varying from zero to 500 volts. The speed of the converter set was 300 to 375 revs. per min., a variation of 11 per cent. above or below the mean speed. There was also the usual exciter set, speed-regulating device, controller on driver's platform, switchboard, measuring instruments, &c., of a similar type to those described by Mr. Ablett. The whole equipment was able to take momentary overloads of 200 per cent. to run for half an hour with 75 per cent. and for two hours with 40 per cent. overload, and its cost was said to have been between £20,000 and £22,000.

At the time of our visit flat bottom rails weighing 90 lb. per yard were being rolled from 2-ton ingots, measuring about 17 in. square. Three stand of housings were being used, and 23 passes were given from the ingot to the finished rail, the total elongation being 27 to 30 fold. Of these passes, 14 were given in the cogging, 4 in the roughing and 5 in the finishing rolls. They were working at the rate of 20 tons per hour, but being short of orders the mill was only operated on the day shift.

To ascertain what power was being taken to roll the rails, and also to see what was being reflected back to the power station, we took 109 readings from the wattmeter at intervals of about 3½ seconds during the rolling of one ingot, and we found that the maximum input to the motor driving the flywheel converter set was 1,400 kw., the minimum 400, and the mean 1,050, being a fluctuation of 33 per cent. over and 62 per cent. under the mean. This is, of course, a comparatively small variation. Simultaneous readings were also taken of the amperes and volts of the variable voltage generators, showing that the maximum power taken by the mill was 4,800 H.P., the speed of the mill being 110 revs. per min. As the maximum power reflected back to the station was 1,875 H.P., the flywheels were absorbing peaks amounting to no less than 2,925 H.P.

As the mean power reflected back to the power station was 1,050 kw. and the output 20 tons per hour, energy was being absorbed at the rate of 52·5 kw.-hours per ton rolled. From published figures relating to this installation the energy taken from the power station is about 20 kw.-hours per ton when cogging and 25 to 60 when rolling bars, girders, rails, &c.

Electric energy to supply the whole works was generated in a power house situated near their blast furnace plant by three turbo-alternators, one being of a modified Parsons type and the other two of the Curtis type. The boilers were fired by waste gas from the blast furnaces. We were informed that, allowing for interest on capital expenditure, but charging nothing for the waste gas from furnaces, energy was being generated for 0·11d. per unit. The cost of electric energy to roll the above rails was, therefore, 5·8d. per ton. Taking £21,000 as the cost of the complete installation, and allowing 10 per cent. for interest and depreciation—and my experience enables me to say that with properly designed electrical plant of suitable size for the work no more is needed—we have £2,100 as the annual capital charge. This is equivalent to 4·6d. per ton, and added to the energy charge of 5·8d., gives 10·4d. per ton as the charge for power, but excluding wages of drivers and other attendants.

The operation of the plant was all that could be desired. The drivers of the old steam engine operated it from the start without the slightest hitch. The advantages of the drive from the purely engineering point of view are obvious: The torque is steady, thus reducing risk of breakdown; it is possible to tell how much power is being taken in each pass, thus enabling the roll designers to obtain the results required with the minimum expenditure of power; the consumption of oil is very much less than in a steam plant (indeed, I recently saw an electrically driven mill at work which has been running now for about 2½ years, and the managing director informed me that the original oil was still in the oil wells, it having only been necessary to take it out once and strain it); the whole control is performed with a single lever; the reversal is prompt; and there is no steam, oil, water and noise to cause annoyance.

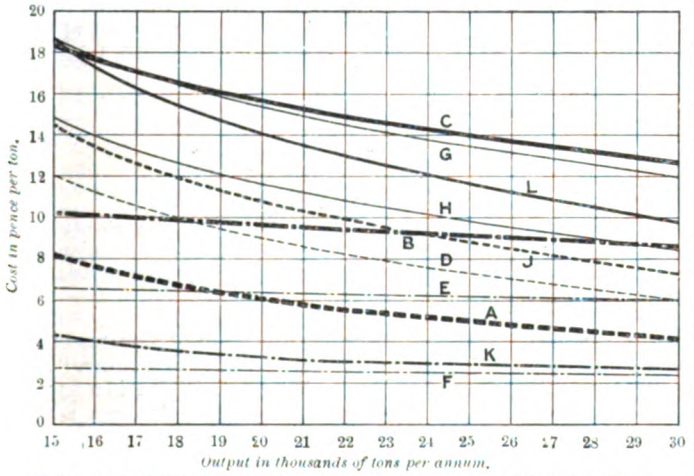
From what I saw at Hildegardehütte and from all that I have been able to learn since, I am convinced that the electric driving of reversing mills has come to stay. It is, however, to mills of large output that it is most desirable to apply it, as with mills of smaller output the capital charges due to the comparatively high first cost of the plant are apt to be prohibitive.

I recently had occasion to compare the cost of driving a section mill, requiring, taking one section with another, about 20 B.H.P.-

Digitized by Google

hours per ton of steel rolled, (1) with a compound condensing reversing engine, (2) with an all-electric reversing drive, and (3) with an electric reversing drive but with the motor of the flywheel converter set replaced by a mixed pressure turbine. As I am not at liberty to give exact figures, I will give others of about the same order of magnitude and preserving the relation of the amounts to each other. To enable the conclusions to be followed I will refer to Figs. 1 and 2, on which the steam drive is indicated by very thick lines, all-electric drive by thin lines and the turbo-electric drive by lines of medium thickness.

Compound Steam Drive.—A twin compound condensing reversing engine suitable for this mill with a barometric jet condenser, electrically-driven hot and cold water and dry-air pumps and cooling tower would cost about £5,000. Taking interest and depreciation at 10 per cent. gives £500 per annum as the capital charge. This is



Capital charge curves in dotted lines. Energy charge curves in chain dotted lines. Sum of above curves in full lines.

FIG. 1.

shown in curve A (Fig. 1) as a rate per ton between limits of output of 30,000 and 15,000 tons per annum, from which it will be seen that at 30,000 tons the rate is 4d. per ton, increasing to 8d. at 15,000 tons, the curve being a hyperbola.

The steam consumption of a compound reversing engine working under rolling mill conditions may be taken at 35 lb per brake-horse-power hour. With boiler plants such as are usually found in steel works and fuel at 6s. per ton, 100 lb. weight of steam can be generated for ¼d., including all boiler plant charges, interest, depreciation, upkeep, wages, fuel, water and the handling of the fuel and ashes. The cost of steam for the main engine is therefore 7d. per ton rolled. To this must be added the cost of current used to drive condenser pumps, say, 1·6d. per ton, bringing the energy charges to 8·6d. per ton. This may be taken as the cost at the maximum output of the mill, but will increase, as the output is reduced, since the rolls will be kept turning round waiting on billets, the condenser pumps will be

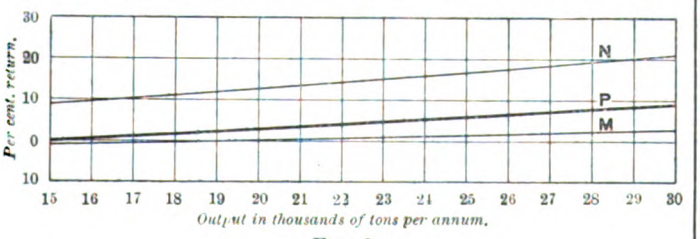


FIG. 2.

kept running full speed to maintain the vacuum, and as the condensation losses in the steam pipes depend mainly on the length and exposed area of the pipes these will also rise somewhat rapidly. We shall be about right if we assume the rate to rise to 10·2d. per ton at 15,000 tons output. This is shown by curve B (Fig. 1).

The sum of the capital and energy charges is shown on curve C (Fig. 1), and will be seen to be 12·6d. per ton at 30,000 tons, increasing to 18·2d. per ton at 15,000 tons output per annum.

All-Electric Drive.—The cost of a flywheel converter set with motor, flywheel, variable voltage generator, mill motor, exciter, speed regulator, controller, switchboard, measuring instruments, &c., will be, say, £7,500—that is, 1·5 times the cost of a compound steam plant. Taking interest and depreciation at 10 per cent. we get £750 as the annual capital charge. This, plotted as a rate per ton, gives curve D (Fig. 1), from which it will be seen that it amounts to 6d. per ton at 30,000 tons, increasing to 12d. at 15,000 tons output.

Taking the overall efficiency of the drive at 62 per cent., we get as input to the motor driving the flywheel converter set 24 kw.-hours per ton. This multiplied by the rate per unit will give the energy charges. I have plotted two curves, E and F, in Fig. 1, the former with current supplied at ¼d., the latter at $\frac{1}{10}$d. per unit. With current at ¼d. per unit, at which rate it can be produced in a fairly large power station using exhaust steam turbines working with the load factor customary in steelworks, the energy charges work out at 6d. per ton. This will increase, as the output diminishes, to 6·6d. per ton at an output of 15,000 tons. This is plotted in curve E. The sum of this and the capital charges is shown on curve G, from which it will be seen that the rate amounts to 12d. per ton at 30,000 tons, increasing to 15·6d. per ton at 15,000 tons output.

It will thus be seen that, with the maximum output assumed, the electric drive is 0·6d. per ton cheaper than steam, with an output of 20,000 tons they are equal, and at the minimum output assumed the electric drive is dearer than steam by 0·4d. per ton.

Suppose, however, that electric energy could be got for $\frac{1}{10}$d. per unit (which should be possible where gas engines using cheap power gas are employed); the energy charges will be as shown on curve F. The sum of curves D and F gives curve H, from which it will be seen that the rate per ton is 8·4d., increasing to 14·7d. at the minimum output. In this case the electric drive is cheaper than steam throughout the whole range.

Turbo-Electric Drive.—This plant has the highest first cost of all, as it only differs from the last in having a mixed pressure turbine substituted for the motor to drive the flywheel converter set, and in addition we require a heat accumulator, also a condenser with its pumps and cooling tower. The cost would probably not be less than £9,000—that is, 1·8 times the cost of the compound steam drive. The capital charges, plotted as before, give curve J (Fig. 1), from which it will be seen that they range between 7·2d. and 14·4d. per ton.

If enough exhaust steam could at all times be provided, no charge need be made for the energy to drive the turbine, as it would be covered by the capital charges on the plant. There would, however, be the current required for the condenser pumps. Under the conditions in which mills work, however, it is impossible to assume that exhaust steam alone would be sufficient to operate the plant, and some charge must be made for live steam. We shall probably be about right if we take rates of 2·6d., increasing to 4·2d., per ton as the cost of live steam for turbine and current for condenser pumps. This is plotted in curve K (Fig. 1). The sum of this and curve J gives curve L, from which it will be seen that the cost per ton is 9·8d. and 18·6d. per ton at the maximum and minimum outputs respectively. Compared with the steam drive there is a saving of 2·8d. per ton, decreasing to zero and becoming more costly by 0·4d. per ton at an output of 15,000 tons.

In Fig. 2 I have plotted the above savings in the rate per ton as a percentage return on the additional capital cost of the electric over the steam plant. With all-electric drive and energy at ¼d. per unit the return on the additional capital outlay of £2,500 is 3 per cent. at 30,000 tons, falling to zero at 20,000, and becoming 1 per cent. at 15,000 tons output, as shown in curve M. With energy at $\frac{1}{10}$d. per unit, the return is 21 per cent. at 30,000 tons, diminishing to 8·7 per cent. at 15,000 tons output per annum, as shown in curve N.

In the case of the turbo-electric drive, we have to earn interest on an additional capital expenditure of £4,000, and the return, as will be seen from curve P, is 8·8 per cent. at 30,000 tons, falling to zero at about 16,000 tons and becoming 0·6 per cent. at an output of 15,000 tons per annum.

The conclusion, therefore, which may fairly be drawn from the foregoing considerations is that for this particular mill, working under the conditions assumed, electric driving would only be commercially practicable with an all-electric drive, and then only if electric energy could be had for something under ½d. per unit. It must be clearly understood, however, that the diagrams I have plotted apply only to this mill, and cannot be taken as generally applicable. Each mill must, of course, be considered on its merits.

There is another conclusion which an examination of the curves leads to—viz., that the larger the output the better the case will be for electricity. Had it been possible under the conditions in which such mills work to increase the output considerably over the maximum I have assumed the turbo-electric drive would become a good commercial proposition, and even an all-electric drive with energy at ¼d. per unit might have been practicable. Indeed, I think it not improbable that we have been dealing in this case with the bottom limit of output at which it just begins to be commercially feasible to adopt an electric drive for a reversing mill.

It is difficult to estimate what must have been the cost per ton of rolling with the original steam engine which drove the mill at Hildegardehütte, already referred to. The first cost of the steam plant, including engine, foundation, pipe connections, &c., could not have

Digitized by Google

been less than £6,000 erected complete, the annual capital charges on which are £600. With an output of 200 tons per shift, 11 shifts per week, and 50 working weeks per annum, the capital charges become 1·3d. per ton. If we assume the overall efficiency of this, the first reversing electrical equipment, to have been 5 per cent., the net power to drive the mill is 40 B.H.P.-hours per ton. A non-condensing reversing engine working under rolling mill conditions will not use less than 60 lb. of steam per brake horse-power-hour. The lowest rate which I have seen given as the cost of steam in Germany was 2 marks per metric ton, equivalent to 0·011d. per pound. The cost of steam is, therefore, 26·4d. per ton, which, added to the capital charges, gives 27·7d. as the cost of rolling with steam. We have already seen that the cost with electricity was 10·4d. per ton, a saving of 17·3d. per ton. With the output named this is equal to, say, £7,800 per annum, a return on the additional capital cost of the electric installation (amounting to no less than £15,000) of 52 per cent. The plant would, therefore, pay for itself in two years. This shows what can be done with a large mill and cheap electric energy, and it is only fair to add that if it had to be laid down to-day, with the experience which has since been gained, the first cost could be materially reduced.

The great advantage of electric driving being that it is easy to ascertain exactly what power is required for each section rolled, to ascertain, therefore, the cost of rolling any section a good way would be to have two diagrams plotted, one to show the capital charges (abscissæ being, say, tons per shift and ordinates rates per ton). A hyperbolic curve giving the capital charges for the whole mill equipment drawn across the diagram would enable the capital charges to be ascertained for the particular output wanted. The other diagram would have abscissæ and ordinates as before, but in this case there would be drawn across the diagram a series of curves giving the product of kilowatt-hours per ton into rate per unit for current. Then running up from the output to the appropriate energy curve the rate per ton would be read on the vertical scale. The sum of these and the wages charges per ton would then give the cost of rolling that particular section.

It is worthy of remark that in Germany, where the flywheel converter drive has been most extensively used, it is to mills of large output that it is applied, such as cogging, billet, rail and girder mills. In one case I saw outputs given of 60 to 70 tons per hour, which, as the curves on the diagrams prove, would be eminently suitable for the purpose, and very substantial savings might be expected. German steel works are (in the case of the larger ones at any rate) mostly equipped with blast furnaces, and as Germany may almost be said to be the home of the large gas engine, there can be no doubt that they are in an exceptionally good position to obtain cheap power. I fear, therefore, that we must admit that our German competitors in the world's markets are in many cases able by their more skilful utilisation of waste energy to roll their steel at lower rates for power than usually obtain in this country. This we cannot allow to continue. A beginning has certainly been made in Britain with the electrification even of reversing mills. At the works of Sir Alfred Hickman a 30 in. cogging and a 24 in. bar mill are so driven, and at the works of the Skinningrove Iron Co. there is a 36 in. cogging mill. The energy for these is generated, I believe, by gas engines using blast furnace gas. Messrs. Dorman, Long & Co. have a 28 in. cogging mill and a 16 in. bar mill, the energy for which is taken from the mains of the local power company. As experience is gained others are certain to follow.

The method of driving rolling mills described by Mr. Ablett in his Paper is not yet very old, and I venture to hope that considerable improvement will be effected, not only to reduce the cost but to increase the efficiency. An over-all efficiency of 62 per cent. surely admits of this. One method of reducing the cost is referred to by Mr. Ablett, where one converter set is used to drive the motors of two mills. We in the steelworks will at the same time have to try and reduce the cost of electric energy. One mode of doing this will be to utilise the heat in the large volume of gases that go up the chimneys of the open hearth furnaces. Some attempts were made in the past by interposing boilers between the furnace valves and the chimneys, but they were abandoned because the draught of the furnaces was interfered with. This difficulty could, I believe, have been easily got over by the adoption of some form of induced draught to draw the hot gases amongst the water tubes of the boilers. It would possibly also be better to generate the steam at low pressure so as to have a better heat gradient between the temperature of the waste gases and the water in the boilers. The steam from these boilers would then be used for turbo-generators.

In my opinion, however, it is to the gas engine that we must look for the real solution of the cheap power problem, and as patents expire and more engineers take up its manufacture we may expect considerable improvements not only from the thermo-dynamic standpoint, but also from that of first cost and freedom from breakdowns. I believe that in the steelworks of the future there will be no reciprocating steam engines at all. The whole of the fuel will be converted into gas, partly, no doubt, in blast furnaces, but also in gas producers, the ammonia will be extracted and the purified and washed gas used both for heating and for power; the steam necessary to saturate the air-blast and fix the nitrogen being generated partly, as I have suggested, by the waste heat from the open hearth furnaces, and partly by the heat in the exhaust gases from the engines themselves. The whole of the power for the works will be generated in a central station and distributed electrically to the various mills and auxiliary machinery about the works. The large reversing mills will be driven either in the manner dealt with by Mr. Ablett in his Paper, by some improved type of flywheel converter, or by the method proposed about a year ago by Messrs. Brown, Boveri & Co. But the medium and smaller mills will, I think, be three-high driven by continuous running motors, as the first cost of any system of driving them electrically as reversing mills will, I fear, at all times be prohibitive.

TESTS ON MICA TUBES.*

BY DR. K. FISCHER.

Summary.—Comparative tests are given showing the superiority of a new type of mica tube containing no paper and practically no binding material. Such tubes, being of mica alone, give very high electric disruptive results.

It is a known fact that the resistance of insulating materials depends partly on their purity and partly on the temperature. The breakdown voltage usually falls considerably with an increase of temperature, and mica is the only material which does not act in this way. It is not easy to work it up into tubes on account of its brittleness, and large pieces cannot be used owing to its high price. Consequently, in making micanite tubes, a good deal of paper is incorporated along with suitable binding material, and this makes it possible to turn out tubes of even thickness and smooth surface having, of course, a much lower breakdown voltage than if they were made of mica alone.

The firm of Meirowsky & Co. has made successful attempts to do away with the use of paper and binding material, and the following is a description of their methods and results. Thin plates are built up out of mica leaves by the addition of some binding material, the thickness of the plates being as uniform as possible. The plates are wound on one another under pressure until a tube of the desired thickness is obtained. The combination of a high pressure with a high temperature tends to drive out the small quantity of binding material, and the whole is compacted into a mass resembling a layer of solid mica. The tubes are then heated for several hours, until the last traces of the foreign substances are removed.

A number of these tubes have been tested in the firm's laboratory at Ehrenfeld according to the usual methods. The inside of the tubes is filled with iron rods, projecting from both ends, and the outside is covered with tinfoil, which, however, is kept at a sufficient distance from the ends. The temperature on the outer surface of the tube is taken by a thermometer, the bulb of which is wrapped in a piece of tinfoil and covered on the outside with a strip of felt. The maximum temperature is not reached till after one or two hours in some cases. The results of the tests are given in the following table, which shows the thickness of the tubes, together with the applied pressure and other particulars. Out of the 108 tubes which were tested, 13 broke down within the hour at temperatures very similar to those given in column 4; the remainder survived till the end of the test, which was limited to one hour. The temperatures were in many cases very high, and from these figures it seems possible to apply pressures in the neighbourhood of 15,000 or 18,000 volts per millimetre to the tubes, when they are at a temperature between 150°C. and 200°C. Such high temperatures are impossible in practice for various reasons; still, it is interesting to note that the figures show the likelihood of a possible improvement in high-pressure machines and apparatus. In so far as the tubes themselves are concerned, it is evidently possible to leave considerations of temperature out of account. It might perhaps be possible with enamelled wire to use smaller sizes in the construction of machines, and to obtain the same efficiency, and the designer may well find something alluring in the fact that these tubes can be used to withstand working pressures up to 7,500 volts per millimetre.

In order to compare the improvement which these tubes show when compared with similar products the curves herewith are given. Curves 3 and 4 are for tubes known under the name of "Pertinax,"

constructed of paper impregnated with resin. Curve 3 is for the tube at ordinary temperatures, and Curve 4 for 80°C., the difference between the two being about 20 or 30 per cent. That for micanite is shown in Curve 2, and there is no sensible difference up to 80°C., the same being true for the pure mica tubes, which are the subject of this article and are shown in Curve 1. The surface of these mica tubes is very smooth and even, much more so than in micanite

tubes of the usual construction; discharges due to unevenness of surface are, therefore, much more unlikely. When struck they emit a metallic sound, and are much stronger than other tubes. These qualities may be very useful in simplifying the construction and windings of high-tension alternators. It is becoming very usual to adopt the American plan of winding the coils in the tubes, and then mounting the complete thing in position on the machine, for which it is evidently necessary to use material capable of resisting a certain amount of rough handling. The mica tubes answer these purposes perfectly well. They can be made quite smooth and uniform with walls only 0·75 mm. thick, being composed in this case of convolutions consisting of very thin plates.

A TELEPHONE RELAY.*

BY S. G. BROWN.

Summary.—The author describes the present form of his telephone relay, which depends on the variation in resistance of a microscopic air-gap. This relay will magnify the very feeblest telephone currents about 20 times. He also describes an electric stethoscope which promises to lead to important developments in medical practice.

This relay is the outcome of six years' study, but has only been brought to its final form during the last eighteen months. Ever since the introduction of the telephone a real need was felt for a telephone relay when it was discovered that the distance over which telephones could be used was comparatively limited. Many inventors have worked on the problem, and it has been declared by eminent telephone engineers to be insoluble. Edison, soon after his invention of the carbon button transmitter, caused an electromagnet to act upon the iron diaphragm and thus turned it into a relay, but it was not a success. Hughes, in his Paper before the Royal Society in 1878, stated that a telephone receiver, if included in the microphone circuit and placed upon the resonant board, caused a continuous sound to be produced. Sir Oliver Lodge, in a Paper read in December, 1898, before this Institution, described a relay, consisting of three or four reeds or tuning forks, each carrying carbon contacts and working in series with one aonther. Each reed was arranged to resonate to one particular musical note, and when this note was passed through the string of relays, it was multiplied in power to a considerable extent. An instrument of this character, however, is not effective in intensifying speech. The invention of the powerful granular

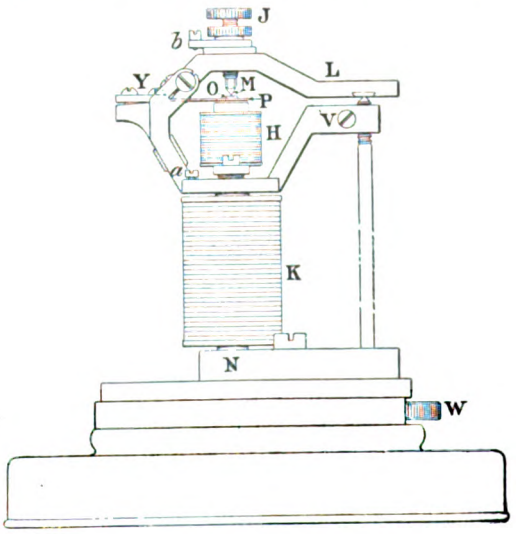

FIG. 1.—SIDE VIEW OF RELAY.

transmitters of the Hunning type stimulated further efforts to obtain the speaking relay, and some progress was made with this type of microphone, particularly in America. These relays, however, are only partially successful, and require relatively powerful currents to work them.

The author's telephone relay has had to be developed along quite new lines. It takes as its basis the researches of J. J. Thomson, Earhart, Kingsley, and others, with regard to the flow of electrons across a microscopic air-gap between two conducting surfaces at different potentials.† Earhart made a series of experiments on the difference of potential required to produce sparks whose length is comparable with the wave-length of sodium light, and he found that when the distance between the metal electrodes falls to less than about 3×10^{-4} cm. the spark potential falls off rapidly with the distance, and seems to become proportional to the distance—that is to say, when the electrodes are placed very close together, within a distance such that the average intensity of force F between the electrodes reaches a value of about a million volts per centimetre, the discharge or current passing is determined by the condition that F, which is V/d, reaches this value (where V is the P.D., and d the distance between the electrodes). If the metallic circuit of a dry cell be interrupted by a minute opening or space of the order of 5×10^{-7} cm., the metal at the point of interruption being platinum, the current will continue to flow round the circuit and across the opening, and any slight alteration in the length

* Abstract of a Paper read before the Institution of Electrical Engineers.

Digitized by Google

of the space, which I shall call the conduction space, will vary its resistance and greatly affect the value of the current that flows round the circuit. This conduction space is therefore exactly what is wanted for the current-varying device of a telephone relay, where microscopic mechanical movements are to be transformed into large current changes. The dimensions of the conduction space are so small that it is difficult to ensure and maintain it by direct mechanical means. The current that flows across the space was therefore made to do its own adjustment, very much in the same way as the current that passes through the arc of an arc lamp is made to strike and maintain the length of the arc.

Fig. 1 is a side view of the instrument with the brass cover removed. N is a permanent magnet, continued by soft iron poles right up to but not touching the "invar" steel reed P. Round the soft iron pole extensions are wound the two sets of coil windings H and K. The telephone currents to be magnified circulate round the winding H and thus by varying the magnetism set the reed P in vibration. M O are the top and bottom metal contact-pieces, which are opened to an infinitesimal degree to form a microphone by the fine adjusting screw W and by the action of the local current passing through the contact and round the winding K. It is by the action of the local current

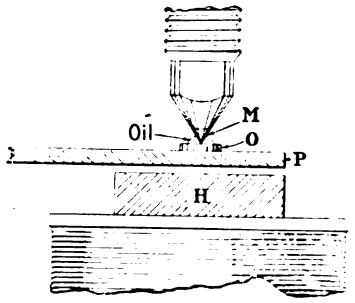

Fig. 2.—Enlarged View of Reed and Contact Pieces.

operating through this winding that the conduction space is formed and afterwards maintained. So good is the automatic adjustment that the instrument may be turned upside down, producing hardly any noticeable alteration in the value of the local current and without any effect on the working of the relay. The regulating winding K must not act when traversed by the rapidly varying telephonic currents—that is brought about by surrounding the iron under the coil by a closed circuited copper sheathing. Eddy currents set up in this sheathing by mutual induction destroy the self-induction of the coil.

Fig. 2 is an enlarged view of the reed P and the contact-pieces MO. In the present instrument the contact is made between metal pieces of hard osmium-iridium alloy. The top contact is pointed, the lower one is flat and is soldered to the reed, both are polished and work under a small drop of thin oil. In earlier instruments the lower contact O was carried by a thin iron disc, the relay was then very sus-

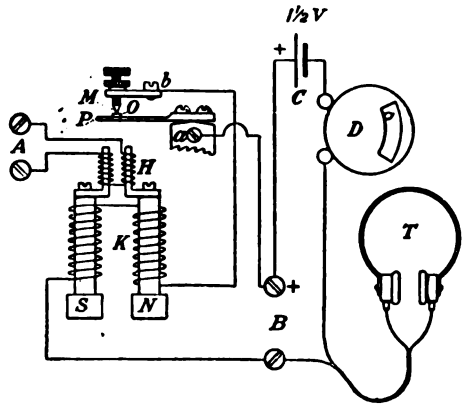

Fig. 3.—Diagram showing Connections of Relay.

ceptible to outside noises. For this reason a reed is now used, it exposes such a small surface to the air that it is practically unaffected by extraneous sound. Fig. 3 shows the connections of the relay. C is a dry cell (this is the normal voltage, which is as high as it is desirable to employ), K the low resistance regulating winding, T the receiving telephone or telephone head-piece of approximately 40 ohms resistance, D is an ammeter; when the microphone contact is opened so as to cut down the local current to half its maximum value the relay is usually at its best adjustment. The telephone currents to be magnified enter by the terminals marked A and circulate through the winding H.

The relay will magnify the very feeblest telephone currents. Speech or signals that are too faint to be heard in the ordinary Bell receiver may be heard clearly through the relay. This property of magnifying feeble telephone currents has made it particularly useful in wireless telegraphy. On replacing the telephone by the relay the increased sensitiveness thus obtained doubles the distance over which it is possible to receive signals. Its utility in this direction has been tested among others by the Admiralty and the Post Office. The relay is not easily affected by extraneous noises and vibration. It

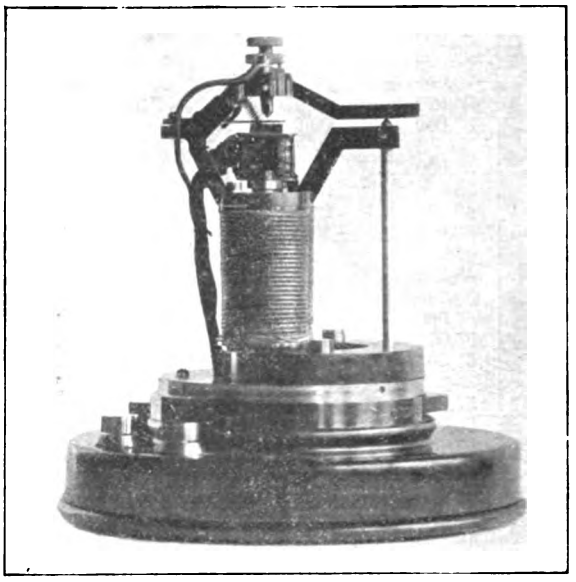

Fig. 4.—Telephone Relay.

can thus be carried on board ship and worked in all weathers. As regards its utility on ordinary telephone lines, speech may be magnified many times in loudness without perceptible loss in the articulation, and it will work with large currents to a point at which the Bell receiver in its local circuit is responding with uncomfortable loudness. Experiments prove that the telephone currents must be increased in strength to the extent of something like 20 times. If still greater magnifications are required, the simplest method would seem to be to employ two relays working in tandem. Their combined power would then be 400 times. In the majority of cases it is not necessary to add to the natural electrical damping of the reed, but if a piece of soft rubber be made to touch it, the voice can be transmitted with greater clearness even than if the conversation were taking place ordinarily in a room. This may be due to the complete absence of echoes. Fig. 4 gives a view of the relay.

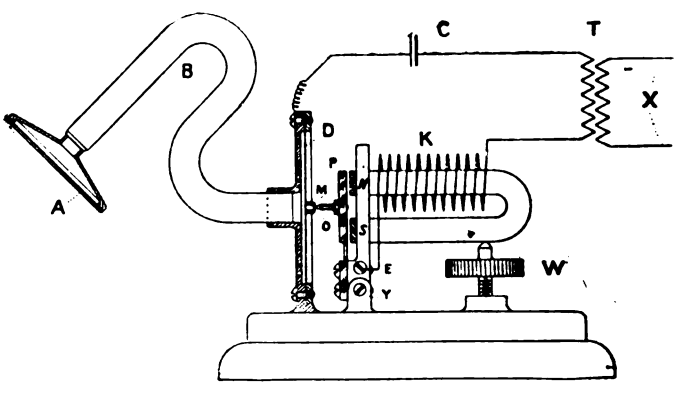

Fig. 5.—Diagram of Electric Stethoscope.

By means of the local regulating winding (Fig. 2) the metal contact MO is transformed into the most exquisitely delicate microphone, more sensitive, there is every reason to believe, than could be formed by light pressure between carbons. Such a microphone has rendered possible the construction of an electric stethoscope, an instrument by the use of which the sound of the heart or other internal organs may be greatly magnified. This, I have been informed, may render it possible to detect in the earlier stages, heart disease, aneurism and gall stones. Figs. 5 and 7 show the stethoscope. A (Fig. 5) is a shallow brass cell faced by a thin ebonite diaphragm, and is placed upon the part of the body to be examined, say the heart; the beating

Digitized by Google

of the heart is communicated to the ebonite diaphragm, then to the air inside the tube B, and thus the metal diaphragm D is set in vibration. MO, as before, are the osmium iridium contact-pieces. M is mounted on the diaphragm, and O on the steel reed P. The magnet NS and the reed are carried by a brass frame E, which is pivoted or hinged at the lower support Y. The conduction space is formed between the contacts MO by turning the fine adjusting screw W, and by the automatic action of the local current from the cell C flowing through the winding K and round the magnet. T is a special telephone transformer of equal windings of, say, 20 ohms resistance in the primary and in the secondary. The electric stethoscope in its present form causes the sound of the heart to be three times as loud as in the ordinary stethoscope. This is scarcely sufficient for practical purposes. But if a telephone relay, such as I have described, be attached to the wires X of the transformer, the two instruments combined raise the intensity of the sound some 20 times and more, and this is ample for all ordinary purposes. At the invitation of two physicians I took the complete instrument to the London Hospital, where it was tested upon a number of diseased heart cases. The sound of the beats given out in the telephones was uncomfortably loud, and easily heard by the patient and all those that stood round, and this even if the telephones were in position on the head of the operator. The stethoscope as used increased the heartbeats to the almost complete exclusion of the shriller or breathing sounds. This has been brought about by mechanically tuning the disc D and the reed P of the telephone relay to the corresponding low note, and by a proper proportioning of the volume of air enclosed by the tube B.

I come now to a subject that it is interesting me greatly—it is still a matter of experiment—the production of a clear and loud-speaking transmitter. Such an instrument would give considerable comfort to the subscriber, and might save hundreds of thousands of pounds worth of copper for the companies. I am under the impression that the carbon transmitter has been developed to its full extent, ceaseless efforts having been directed to this end by the engineers of the large telephone companies. To make progress towards an ideal transmitter, carbon had, therefore, to be abandoned, not because of any serious defect in its microphonic qualities, which are good, but because of its bad conducting power. It would not transmit enough energy. One must pass much current in order to speak loudly, and a material was wanted that not only would conduct well, but would change its resistance to pressure more readily than carbon. I am pleased to say that I have discovered something that carries out my wishes well in both of these directions.

During some experiments with the telphone relay, attempts were made to dispense with the regulating winding and form the microphone by the mere pressure of the electrodes one against the other as with carbon. With gold, platinum, palladium, and rhodium, it was not possible to do so. On the contrary, a microphone could be formed by light pressure between the following: Iridium, ruthenium, osmium-and osmium-iridium alloy. They are arranged advancing in the order of their effectiveness, which is likewise the order of their hardness. With iridium the action was only just shown, while osmium-iridium alloy makes a microphone that can carry large currents, stand high temperatures, and is exceedingly sensitive to small changes of

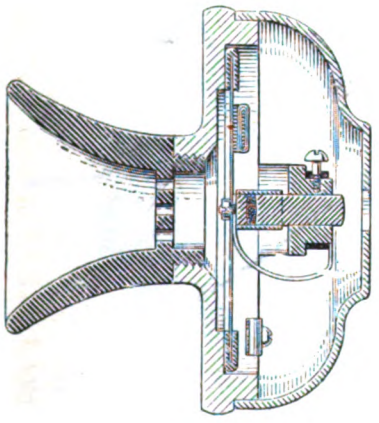

Fig. 6.—New Transmitter.

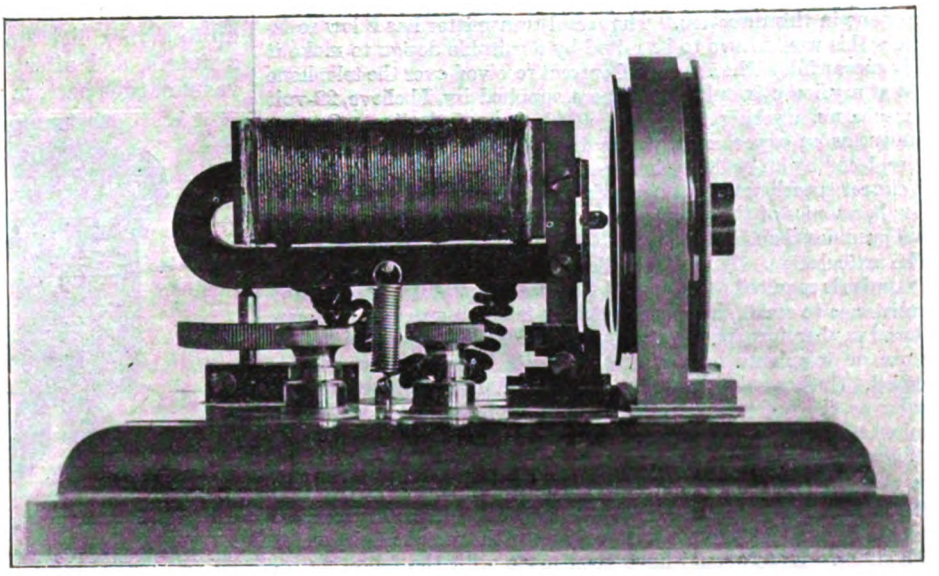

Fig. 7.—Electrical Stethoscope.

On other occasions, during private experiments, the instrument has been tuned so that nothing but the breathing sounds were audible. This power of discrimination should be of service in allowing the independent examination of various organs of the body. Replacing the telephone head-piece by a transformer, the stethoscope has been joined to the telephone service in my house, and for the sake of experiment, the sound of the heart has been transmitted over several miles of telephone line to doctors and friends in various parts of London. All reported that the sounds received in the telephone were as loud and clear as when heard locally. The line, therefore, does not appear to produce much loss or distortion. This trial proved that it is now possible for a specialist in London to examine a patient, say, in the country, stethoscopically, and to arrive at a correct diagnosis.

In consequence of its sensitiveness the apparatus is padded and guarded as far as possible from all outside disturbances, and the patient should be examined in a quiet room. If the instrument is provided with a small funnel in place of the tube B, it will pick up and magnify the slightest sound, and ordinary speaking may be increased to a deafening shout in the telephone. Such an instrument, when properly constructed for the purpose, may be of use to those who are afflicted with deafness. The relay has been used on the electrophone system, and by its aid, damping the reed with a piece of rubber, the speaking and music from the theatres are rendered with loudness and greater clearness than it is possible to have on the telephones supplied by the company, and by adding a loud speaker with trumpet the sounds can be heard in the room.

pressure. This alloy is by far the best of the whole series, as it is the hardest, and although expensive, can be readily purchased as natural grains or granules, sifted to any desired uniform size. As regards the effectiveness of carbon, I should be inclined to include it in the series between iridium and ruthenium. The chemical properties of carbon, ruthenium and osmium have likewise much in common, in that they resist the action of all acids, and are carried off as a gas by oxygen when strongly heated. Ruthenium and osmium are of little value for microphonic purposes if purchased in their commercial form as grains or powder. The grains must be first fused into a bead and then crushed into granules. This may account for the failure of previous experimenters who, in their endeavour to compete with carbon, tried nearly everything that could be mentioned, including ruthenium and osmium, but without success.

Several "solid back" transmitters have been taken and altered in various ways to make use of the new metal. In one case the ordinary carbon electrodes were entirely removed and replaced by sheet iridium-faced ones $\frac{3}{16}$in. in diameter; these electrodes were separated by a distance of $\frac{1}{20}$ in., and the space between was nearly filled by 3 grains weight of very fine granules of osmium-iridium kept in place by a rubber tube. This new transmitter would take permanently a current of $\frac{3}{4}$ ampere from a 2-volt accumulator. It was connected to the telephone service through a large transformer, which had a low-resistance primary of only $\frac{1}{10}$ ohm. The ordinary carbon transmitter, supplied in the usual way from the central battery, was kept in position in series for purpose of comparison. The results of several trials were as follows: Speaking on both occasions

Digitized by Google

with equal force, first, directly into the mouthpiece of the carbon transmitter, secondly 12 in. away from the mouthpiece of the metal transmitter, the same volume was given in the receiving telephone. When the new transmitter was spoken into at a distance of 3 in. the sound was two or three times louder than is at present normal, and when spoken into directly, the sound at the far end was uncomfortably loud and the voice could be heard with ease 3 yds. away from the receiver. In all cases the articulation was clearer and crisper with the metal than with the carbon transmitter.

The first difficulty to contend with occurred after the instrument had been in use some months. This was a gradual weakening of the power of transmission, which was eventually found to be due to the iridium faces of the electrodes becoming superficially oxidised. To remedy this the iridium has been replaced by gold, which so far has proved satisfactory. Another improvement was to cone inwards the faces of the gold electrodes; this is to prevent the granules from unpacking, as they had previously a tendency to do when worked between plane faces.

An osmium-iridium granular transmitter has been constructed embodying all these later improvements (*see* Fig. 6); the electrodes have a diameter of $\frac{1}{4}$ in., and it will work permanently with 1 ampere at 2 volts. When joined to the telephone circuit and spoken directly into, the distant receiver will respond with overwhelming loudness. Such an instrument could be fitted in subscribers' premises where long-distance telephony was much in use, and distances could be spoken over, which at present offer considerable difficulties. As most of the transmitters in London are supplied with current from common or central batteries at the exchanges, it would be important to adapt the new instrument to this system, but up to the present nothing has been done in this direction. The metal transmitter has a low resistance; this would have to be raised by a suitable design to make it really successful. The amount of current received over the telephone wires at my house is only 0·06 ampere, supplied by, I believe, 22-volt accumulators, working through the 360 ohms of the line. On one occasion, as an experiment, the central battery carbon transmitter was replaced by an ordinary low-resistance metal one, and at the far end clearer speech was obtained, which was as loud as before. The upper harmonics of the voice are more faithfully transmitted by the metal granules than by the carbon—this accounts for the superiority in the articulation. A much smaller quantity of the metal powder or granules is required as compared with carbon, and its sensitiveness in resistance to small changes of pressure is much greater; the new material is, therefore, peculiarly adaptable for the purposes of a relay for use on telephone lines where moderate magnification only is required. Such a relay has been constructed using osmium-iridium powder as the resistance varying medium; it is simple in design, requires no adjustment, and so far gives a moderate magnification with good articulation.

APPENDIX.

Referring to the telephone relay, the efficiency of the microphone for speech transmission depends largely upon the metal employed for the contact. Experiments have been made with the following results: The metal must be unoxidisable. Thus materials like brass and aluminium are useless. If they partially oxidise like steel and silvers the magnifying power is small. With the following, good results were attained: Pt, Pd, Rh, Ir, Ru, Os, and osmium-iridium alloy. Carbon has been tried for one or for both of the contact-pieces; the magnifying power is then smaller than with the metals, and less current can be sent through, due to its greater specific resistance. Gold, due to its complete absence of surface oxidisation, makes an unstable contact, and the relay will buzz, very much after the fashion of an electric bell, under all ranges of adjustment. (Soft pure gold makes the best contact for an ordinary relay of any material that I am acquainted with.) Even with the metals of the platinum group the relay can be made to buzz by cleaning the contacts with a cloth, but stability of working can be again secured by oxidising the surface, by exposure to the air, or, what is much better, by applying thin oil to the surfaces of the contact. The nearer the relay is to this buzzing point the greater its sensitiveness; it is therefore advisable to clean the contact so as to obtain the buzzing action and to stop the action by the application of a small drop of thin oil. The harder the contact metal used the clearer the speech through the relay. With soft platinum the higher harmonics are more or less absent, but with osmium-iridium the articulation is quite clear and crisp.

Microphones are sometimes liable to produce faint bubbling and squeaking sounds; this is due, I think, principally, to want of hardness in the contact-pieces, especially if the upper bruises the lower piece. This sound can usually be stopped by shunting through a suitable resistance the winding of the telephone circuit. A microphone formed between two hard metals can touch only in one spot. As half the energy liberated from the local battery is normally dissipated at this point, the rise of temperature there may be very considerable. This heating puts a stop to any great handling of power by a single contact. For these reasons it is not advisable, with the normal voltage to pass more than, say, $\frac{1}{4}$ ampere; if the current is too great the sensitiveness will decrease with time; but if the current is kept small, say of the order of $\frac{1}{10}$ ampere, the delicacy may be perpetually maintained. It is fortunate that the harder varieties of the platinum group are the ones that are able to stand the higher temperatures.

Reference is finally made to some rough tests of a special form of the author's telephone relay and to the fact that there is still much to be done before the two-way repeater is practicable.

AERIAL TELEPHONE LINES ON THE PUPIN SYSTEM.*

NOTES ON A PAPER READ BY A. EBELING.

BY B. S. COHEN.

Summary.—Particulars are given of the loading adopted on various overhead telephone lines in Germany; and of the results obtained. Some particulars are also given of the cost of loaded lines and the financial results to be expected from such lines.

Dr. Ebeling describes the result of tests made by Messrs. Siemens & Halske assisted by the State Post Office. One of the earliest troubles experienced in the application of Pupin coils to aerial wires was the destructive effect of lightning. Owing to the necessity of maintaining the insulation of the line up to a very high standard, it was decided to employ earthed arresters, and after some experience bridged arresters of the vacuum tube pattern were adopted, and these were so arranged

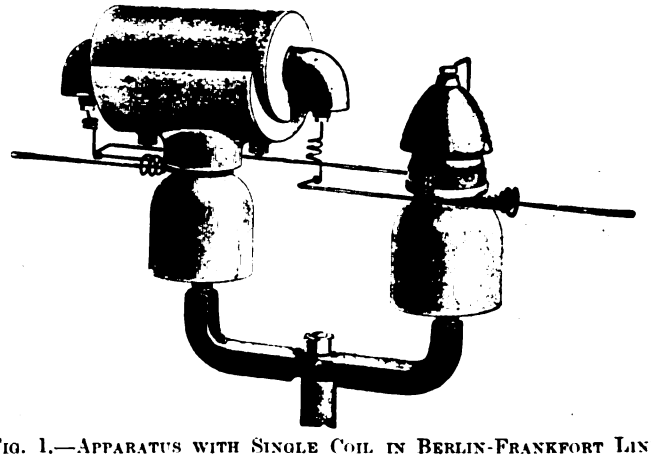

Fig. 1.—Apparatus with Single Coil in Berlin-Frankfort Line. (First nstallation.)

that if the glass tubes were shattered by the discharge the electrodes would come into contact, thus completely short-circuiting the loading coil.

These arresters have been found to protect the coils perfectly, even in cases where the lightning discharge has been strong enough to fuse the line wire. All the earlier equipments consisted of separate inductance coils in the A and B wires of the loop. The first line loaded was between Berlin and Frankfort-on-Main. This line was 580 km. long, and a 2·5 mm. bronze line was used with coils spaced at 5 km. The coils had an effective resistance of 8·7 ohms and an effective inductance of 0·11 henry. The average insulation of the loaded line was about 10 megohms, and consequently leakage played a negligible part in the attenuation.

The loaded line could be compared with a 4 mm. line 580 km. long run on the same poles and a 5 mm. line which took a slightly different route and was 540 km. long.

The relative transmission values of these lines observed by test confirmed the calculated values embodied in the following table.

It should be noted that the conductor termed bronze on the Continent nearly corresponds to the hard drawn copper used in this country. For example, the 2·5 mm. line has a resistance of 7·7 ohms per kilometre loop when unloaded and a

* Dr. Ebeling's Paper was read before the "Elektrotechnischer Verein" and was published in the "E.T.Z."

Digitized by Google

Line.	Effect. res. in ohms per km.loop.,	Inductance in henrys per km. loop.	Mutual capacity, mfds. per km.	Attenuation constant, a.
5·0 mm. bronze	1·92	$1·86\times10^{-3}$	0·0063	0·00176
4·0 mm. ,, ...	3·00	$1·94\times10^{-3}$	0·0060	0·00262
2·5 mm. ,, without coils...	7·70	$2·14\times10^{-3}$	0·0055	0·00591
2·5 mm. ,, with coils	11·18	$46·10\times10^{-3}$	0·0055	0·00193

2·5 mm. English copper line has a resistance of 7·1 ohms per kilometre loop, or very little higher conductivity than the German bronze conductor. The loaded 2·5 mm. line corresponds to an unloaded 4·7 mm. line.

The following is a comparison of the attenuation lengths of the lines given in the previous table :—

Line.	Attenuation length, al.
5·0 mm.	0·95
4·0 mm.	1·52
2·5 mm. without coils	3·43
2·5 mm. with coils	1·12

Dr. Ebeling considers an aerial line to give good talk when $al=1·5$ and sufficiently practical talk if $al=2·5$. The limit of practical audibility is taken as being $al=3·5$ to 4·0.

It is interesting to note that when the terminal loops connected to the loaded line were so short that considerable reflection loss was experienced terminal transformers were inserted to diminish the reflection effect.

Measurements were carried out on the Berlin-Frankfort lines using a dynamometer. A constant sending current of 8·8 milliamperes at frequencies ranging from 600~ to 1,800~ was used.

Fig. 2.—Lightning Arrester without Heavy Current Protector.

Fig. 3.—Lightning Arrester with Heavy Current Protector.

The results, however, are stated to have been unsatisfactory, which was only to be expected, seeing that the sending current was excessive and the dynamometer was unsuitable, as it had an effective resistance of 400 ohms and an inductance of 0·4 henry.

A number of experiments were also carried out using a form of bolometer, but as the particular instrument used was considerably more insensitive than the dynamometer no improvement in the accuracy of the results was obtained.

Turning now to the mechanical details of the Berlin–Frankfort equipment, Fig. 1 illustrates the single coil mounted on a porcelain insulator, together with the vacuum tube protector.

Fig. 2 shows the vacuum tube protector without the outer case, which is itself shown in Fig. 3. This outer case is in halves, and has serrated edges, and in the event of the glass fracturing the halves are brought into contact, thus short-circuiting the loading coil. Fig. 4 shows apparatus mounted on pole.

Berlin–Stralsund Bimetallic Line.—After the Berlin–Frankfort line had been equipped and tested it was decided to equip a bimetallic line, *i.e.*, a copper-covered iron line, with Pupin coils, for further experiments, and the existing Berlin–Stralsund line, 240 km. long, of 4 mm. bimetallic wire, was chosen. The coils, at 4 km. intervals, were fitted in pot-shaped porcelain cases (Fig. 5), while the lightning protectors remained the same as before. This new form of coil pot was resorted to because the Berlin–Frankfort apparatus was not perfect from a mechanical point of view.

This line also showed a great improvement in speech after fitting with coils.

Hamburg–Konigsberg Bimetallic Line.—The 920 km. 5 mm. bimetallic line between Hamburg and Königsberg was then equipped with coils, using the same apparatus. The talk on

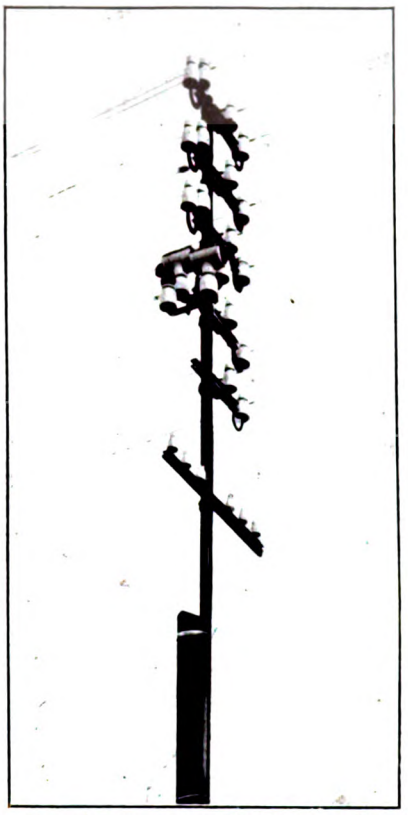

Fig. 4.—Single Coil Apparatus in Position on Berlin-Frankfort Line. (First installation.)

this line without coils may be considered equivalent to a 3 mm. bronze line. This line, however, was much affected by disturbances from high-speed telegraph circuits, which were run on the same poles. The loaded line was, therefore, first transposed at intervals of 500 metres, and this, whilst appreciably reducing the disturbances, did not remove them altogether. The principal source of the disturbance was then traced to a

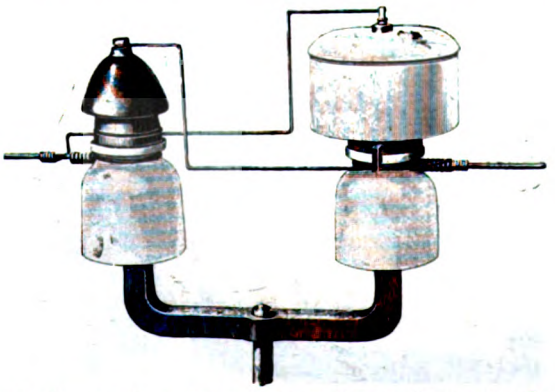

Fig. 5.—Single Coil Apparatus on Berlin-Stralsund Line.

Siemens rapid telegraph line, and considerable improvement was effected by inserting inductance into the line in order to reduce the peakiness of the telegraph waves. The loaded line was naturally more susceptible to disturbance than the unloaded line, owing to the greater transmission efficiency of the former.

A second equipment was now carried out on the Berlin–

Digitized by Google

Frankfort line with coils mounted in a similar manner to those on the Berlin–Stralsund line. Although greater efficiency was reached than in the case of the earlier equipment, the mechanical details were still found to be imperfect. During the cold winters of 1906 and 1907 a considerable proportion of the porcelain caps were cracked, from which bad contacts and the introduction of moisture into the cases resulted.

A third equipment was therefore installed on the Berlin–Frankfort lines. In this equipment the weight of the apparatus was considerably reduced, and the coils were placed in metal cases which were completely soldered up. Separate coils were still used for the A and B lines. Fig. 6 shows the apparatus mounted on the pole, and Fig. 7 gives the details.

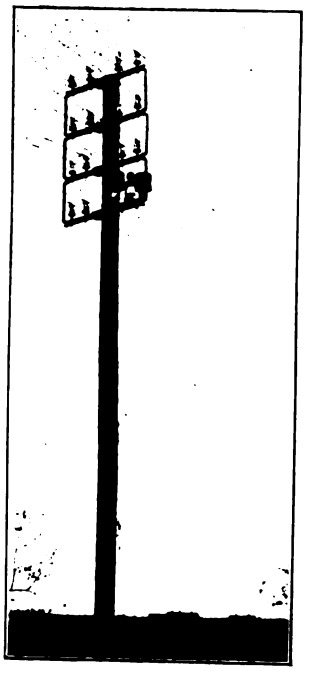

Fig. 6.—Single Coil Apparatus with Lightning Protector on Separate Insulator in Position.

The coils had a mean inductance of 0·105 henry and a mean effective resistance of 5 ohms. The calculated attenuation constant was 0·00176, which implied that the 2·5 mm. loaded line would be equal to a 5 mm. unloaded line, and this was found to be borne out by practical test. A further series of tests was carried out by a special speech method devised by Prof. Breisig, the details of which are not given. Comparisons were made of the loaded line against 5 mm. and 4 mm. unloaded lines, and 200 km. of 2 mm. line was connected to the end of the line under test, so that when the loaded line was tested the reflection losses would be reduced to a minimum. The attenuation length *al* of the 200 km. of 2 mm. line was 1·8. The following table gives the results of this test :—

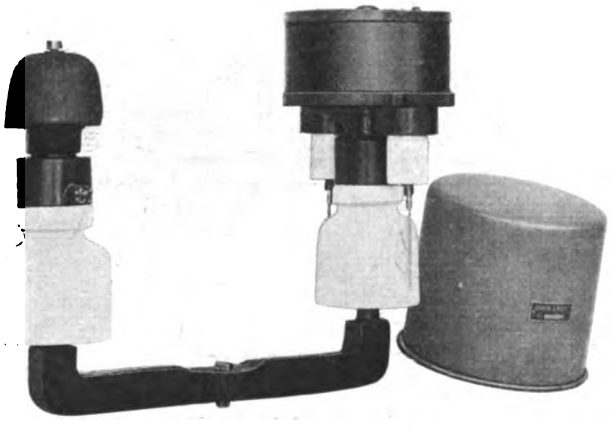

Fig. 7.—Single Coil Apparatus with Metal Cover Removed.

Lines.	*al* observed.	*al* calculated.
5 mm. + 200 km. 2 mm.	2·9	2·8
4 mm. + 200 km. 2 mm.	3·3	3·3
2·5 mm. with coils + 200 km. 2 mm. ...	3·4	2·8

It will be noticed that the observed value of the loaded line is equivalent to the observed value of the 4 mm. unloaded line. Tests were also made on the loaded line with and without the unloaded terminal line, but these appear to be contradictory, as the observed result should have been better when the loaded line is terminated by the unloaded line, and the reverse of this appears to have actually been the case. Without further details, one is inclined to attribute the error to the method of making the test.

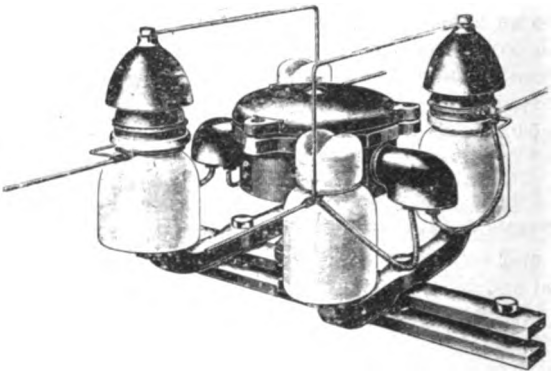

Fig. 8.—Experimental Double Coil Apparatus with Separate Lightning Protectors on Berlin-Magdeburg Line.

The Berlin–Frankfort line has now been working with the new apparatus for about a year without the least mishap, although the line has gone through the thunderstorm period of last summer and the cold period of last winter.

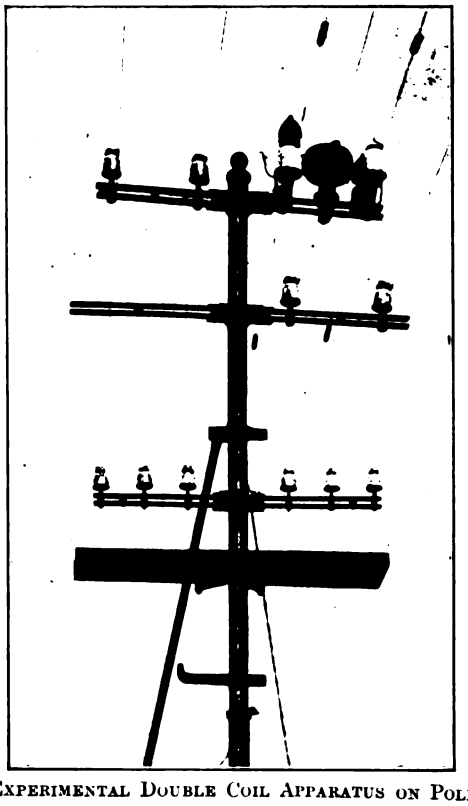

Fig. 9.—Experimental Double Coil Apparatus on Poles, Berlin-Magdeburg Line.

Dr. Ebeling refers to a series of tests made by means of an oscillograph, which appeared to confirm the improvements obtained in practice. He gives no further particulars, however but states that further tests are required. It was now decided to equip some lines with double coils—*i.e.*, coils having the two windings for the A and B lines wound on one core.

Digitized by Google

After the Berlin Magdeburg line previously referred to had been reinstalled for some considerable time with double-wound coils, which gave satisfactory results, the use of double coils was generally adopted. Fig. 8 shows the complete apparatus as now used, with the coils enclosed in metal case, and Fig. 9 the same apparatus mounted on the pole.

A considerable number of these coils have been employed by the Austrian Government and also by the Royal Prussian Railway.

In one district, where in the summer of 1908 very violent storms occurred, not a single coil was damaged by lightning. The Paper concludes with a consideration of the economic value of loading aerial lines.

Dr. Ebeling first points out that a 3 mm. bronze line loaded is at the least equal to a 4·5 mm. unloaded line, allowing for reflection losses. Then, as 1 kg. of bronze costs 1·70 marks,

1 km. double line of 3 mm. bronze costs	220 marks.
1 km. „ „ 4·5 mm. „ „	500 „
Saving by using 3 mm. bronze	280 „

The price of coils when spaced 8 km. apart is about 50 marks per kilometre, so that 1 km. of 3 mm. loaded line costs 270 marks. Approximately, therefore, the loaded line costs half that of an equivalent unloaded line.

With a 600 km. loaded line of 3 mm. bronze, therefore, the saving would be about 138,000 marks (£6,900).

The Paper was followed by a discussion, which was not published at the time these notes were made.

This Paper is of considerable interest, as it gives a very good idea of the progress made in Germany in the loading of overhead telephone lines. The experiences of others in the loading of overhead conductors has led to the general conclusion that the insulation of the lines must be maintained at a decidedly high figure and doubt has even been expressed in some quarters as to the possibility of maintaining lines at a sufficiently high insulation in a damp climate to enable the advantages of loading to be realized. It is permissible, however, to infer from Dr. Ebeling's Paper that no special difficulty from low insulation has been met with in Germany.

THE APPLICATIONS OF ELECTRICITY TO FIELD ENGINEERING.*

BY COL. R. E. B. CROMPTON, C.B.

The applications of electricity to field engineering may be divided into three heads: first, for army signalling, which, when electricity is used, has advanced through the various forms of the telegraph, field telephone and, last, but most important, that of wireless telegraphy. The second is its application as a ready and convenient means of producing light, either in large units for searchlights or projectors, or in smaller units for carrying on operations by night, or for lighting field hospitals. The third is that by which the electric transmission of power can be made available for providing power plant at points where such is needed in field operations. Among these may be mentioned pumping plant for field water supply, power for driving machine tools in field workshops; and it is probable that at no distant date electro-chemical developments might be made available for the purification or sterilisation of water supply, and for other sanitary or hygienic purposes.

On the question of the field telephone some personal experience in the South African War may be useful to record. When studying the equipment for the working of the field searchlights it was decided to take out a certain number of bicycles, on which could be mounted reels carrying wire which, it was hoped, it would be possible to lay on the veldt as a convenient means of communication between the generating plant and projectors. It was found, however, that such a short length of insulated wire could be carried that a few miles of very fine uninsulated No. 22 gauge copper wire was taken out on reels, and this was found to be unexpectedly useful, for the surface of the veldt was rarely insufficiently dry to insulate this wire, so that it was possible to obtain audible speech through the Swedish cavalry pattern field telephone equipment up to distances of several miles, and what was still more unexpected, although these circuits were frequently interrupted by stray cattle, or by vehicles cutting the wires and dragging the several ends some distance apart, it was found that it was still possible to get audible speech through the very considerable gap at these points of fracture, and that the speech was very good when the two ends, although separated, had been dragged for some little distance, as was usually the case, so that the few yards of wire close to the fractured ends were practically parallel to one another. This fact is mentioned, for it shows how easy it was to provide a very simple means of telephone communication by carrying on ordinary bicycles reels of wire weighing only 20 lb. or 30 lb. The radius of action of this equipment would, of course, be greatly increased if the modern motor bicycle were used. Under such conditions great lengths of this same wire could be carried, and there is no doubt that improvements can be made in the condenser portion of the transmitting and receiving apparatus, which no doubt was the cause of our being able to obtain audible signalling through such considerable air gaps.

As regards wireless telegraphy, during the manœuvres which have taken place during the last two or three years, the author has paid close attention to the working of the Muirhead equipment, which is the one that has, up to the present, been used both by the Royal Engineers and by the Wireless companies in London, under Colonel Bain, and has formed an opinion that this wireless equipment is capable of very great further development in the direction of making the transmitting and receiving stations entirely self-contained and self-propelled, in other words that each station should consist of one or possibly two motor cars, carrying the generating and transmitting machinery, and also supporting the poles or antennæ or other means of keeping stretched the transmitting and receiving wire.

After referring to the early history of electric lighting, and to the difficulties attendant on the use of glass mirrors owing to gun fire—a difficulty which was overcome by mounting on springs the Mangin mirror—the lecturer said that the use of projectors was rapidly extending for naval purposes, and also at defended ports where large searchlights were fixed in emplacements so as to enable the approach of the enemy to be observed during the darkest nights whether as a fleet, squadron, single vessel or even torpedo boat.

At the time of the South African War, however, the problem had to be faced not only of making the searchlights or any other artificial lights we might wish to use conveniently portable, but also to devise the simplest method of generating the current required. Eventually it was decided to employ small traction engines; these drove dynamos by belts, the dynamos being mounted on brackets fixed in front of the smoke box. This arrangement was used in connection with the projectors which, towards the latter end of the war, were mounted in fixed positions at various points in the Transvaal and the Orange Free State, and did good service in sweeping the veldt with a strong beam. They were also very effective in assisting to protect some of the collieries on which the supply of coal for Army purposes depended, and no doubt the employment of the searchlights on the headworks of these collieries enabled the defending force to be greatly reduced. Probably the main reason why the projectors themselves were so seldom at first employed in field work, was that the engines and dynamos were found so useful for supplying electrical energy for lighting purposes for the reinstatement of bridges, for certain deviation work on the railway reconstruction, and, most important of all, at points where stores required to be transhipped by night from the railway to the A.S.C. waggons, that the three sets of engines and dynamos were always at work and could not be spared for work admittedly experimental in connection with projectors.

The proper position of a searchlight emplacement in respect to the guns the firing of which it is intended to aid, is a problem which has been much discussed, and on which very varying opinions still obtain. Personally the author is against fixed lights. He believes that artillery fire at night can be rendered most effective by the searchlights being movable, along a certain track in a covered way parallel to the front to be defended, the position on this track being communicated by signal from the officer directing the artillery fire, who again is informed by the gun layers which positions give them the best sight of the fairway and of the enemy's approach. At any rate, he believes that as far as we know the best practice for placing searchlights in defended positions is not in fixed emplacements, but that covered ways should be provided along which several of the searchlights can be easily moved and directed, in the manner above described.

In the early days searchlights, both on land and sea, were provided with inclined lamps; at sea these at first were nearly always hand worked, but on land, in a few cases, they were provided with automatic means of maintaining the length of the arc, but the lamps taken out to the Cape were automatic and provided with horizontal carbons, and this arrangement has since been practically universally adopted. The lamp now used by the Admiralty, and designed at Chelmsford, is the same pattern as the lamps designed

* Abstract of a lecture delivered at the Royal Engineers' Institute, Chatham.

Digitized by Google

and used in South Africa. Much improvement has been made in the mirrors. The Mangin mirrors were very effective, but very heavy. Their weight threw the whole projector out of balance, and Parsons, Chance and others in this country produced glass mirrors of much less weight and quite as effective. Just about the time of the war Cowper-Coles invented the palladium-faced metallic mirror, and some of these mirrors were taken to the Cape in addition to those of the usual glass pattern. Mr. Parsons also distinguished himself by improvements in methods of grinding parabolic mirrors, and succeeded in getting short focus mirrors to work, which

FIG. 1.—36 IN. MILITARY PROJECTOR.

were far more effective than the long focus spherical mirrors which had been hitherto used, and further than this he devised methods by which a beam could be projected through a narrow vertical slit, such as a porthole, the searchlight itself and the men working it being thus protected from the enemy's fire.

The latest thing now under discussion are the gold-faced mirrors, which have been introduced here and abroad, and which, although they are slightly, that is to say about 5 per cent., inferior to silver-

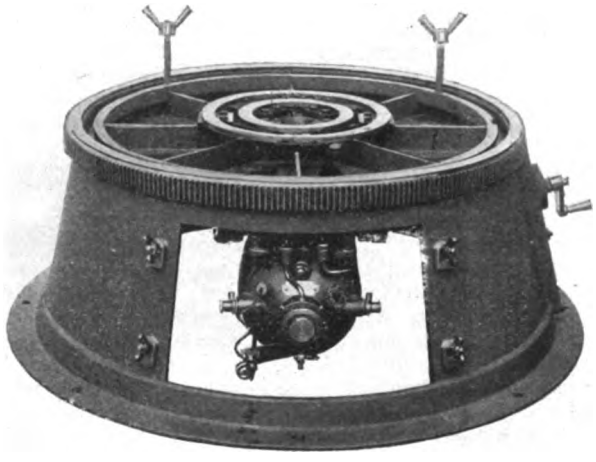

FIG. 2.—BASE OF 36 IN. ELECTRICALLY CONTROLLED PROJECTOR, SHOWING TRAVERSING MOTOR.

plated mirrors when both are equally well polished, yet the gold preserves its surface, and hence its reflecting power. so much better than silver, that after a few hours' exposure the gold-plated mirror has the advantage.

Recently a good deal has been done in the perfecting of searchlights for naval purposes. They have been made automatic, all movements worked electrically and controlled from the bridge, and a great deal has been done to render them easily dismounted, and taken below during daylight hours.

As has been already pointed out, after all the means of rapidly and economically producing artificial light for night operations at railhead or other railway reconstruction works, reconstruction of bridges or of deviations is probably the most important use for electricity in field service. The equipment at the Cape was of the crudest description, and while valuable experience was gained with it, as far as the author is aware no attempt has been made to standardise or to reproduce in a more permanent form the very crude systems of derricks, poles, cable reels and other appliances which are necessary for these methods of lighting.

One of the difficulties met with in working field searchlights, as well as in working the detached installations, was the great weight of the cables that have to be handled. This was because low-pressure current was used. All the searchlights were arranged in parallel, consequently the currents dealt with were large. It is evident that for the future it would be far better to standardise all the cables so as to be of the right section to carry about 10 amperes, and to generate at about 1,000 volts. To arrange small arc lights for depot lighting purposes in series circuits, and for searchlight or for lighting by means of incandescent lamps to use motor transformerr to bring down the 1,000-volt to a working pressure of 80 voltss which is a convenient one to use at the terminals of the lamps of the searchlight. Although this arrangement was fully worked out and laid before Army Headquarters at the time, as far as the author is aware it has not been acted on. Even at that time there would have been no difficulty in placing the motor transformer, that was

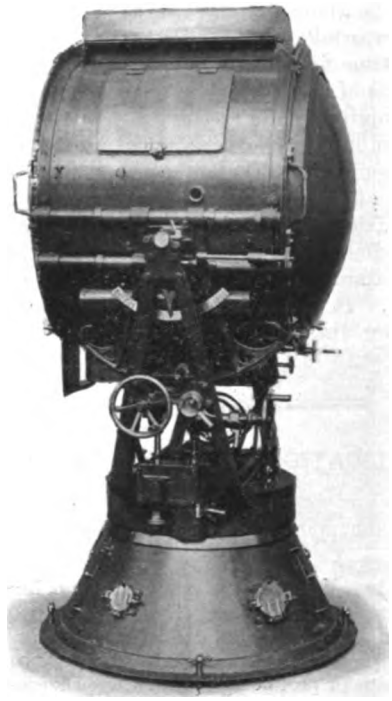

FIG. 3.—36 IN. ELECTRICALLY CONTROLLED PROJECTOR.

then necessary, on the limber of the searchlight. In these days of auto-transformers the matter can be very much simplified. Not only is the transformation effected with one revolving armature, but the ratio of pressure transformation can be varied through very wide limits. The author is therefore justified in thinking that the current for the field searchlight equipment should always be generated in such a manner that the cables need only be of a size to carry 10 amperes, and that the transformation be effected at or near the point of employment.

It is obvious that the two great commercial developments of arc lighting which have taken place during the last few years, namely, that of enclosed arc lamps with the reduction in the size of the unit, and the great reduction in the labour of re-carboning, and again for larger units the use of flame arcs, will both of them be advantageous for the lighting of such night operations as were found necessary in South Africa. But for other uses, such as those that are about to be described, the metallic filament lamps which are now being so rapidly introduced will also take their part. Artificial lighting by means of incandescent lamps was found of great use in the field hospitals. Many difficult and dangerous surgical operations were able to be carried on during the night, and life was thereby saved, and everywhere it was generally admitted that the work of our great field hospitals was greatly helped by our being able to fit them with electric light throughout.

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

Towards the latter period of the war two or three systems of defence lighting using incandescent lamps were used. It was found that it was possible to fit up wire entanglements and other spots, at which it was desirable to have early notice of the approach of the enemy, with incandescent lamps which were so screened and directed and controlled that the sentry on hearing any noise could switch on a particular circuit of lights at some distance from himself which thus enabled him to locate a scout or spy endeavouring to obtain access to the defended position. This use of artificial lighting for the defence of fixed posts deserves further working out.

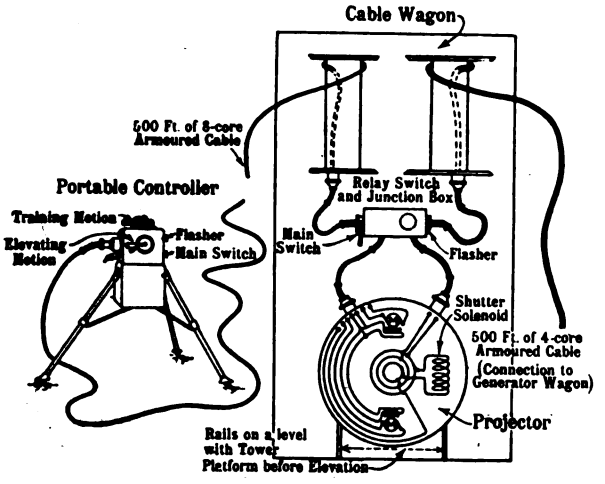

FIG. 4.—DIAGRAMMATIC ARRANGEMENT OF CABLE WAGON AND CONTROLLER FOR MILITARY PROJECTOR.

The third group, namely, the use of electric transmission of power, has not as yet been taken at its full worth. The fact that power can be supplied by overhead or buried cable to considerable distances from the generating source will no doubt enable many operations demanding the use of power to be carried on in isolated redoubts or other defended posts. It is hardly necessary to enumerate the number of such applications. Many defended posts are placed on high ground where the water supply is very difficult to obtain, and where hitherto it has been found necessary to send horse-hauled water tanks under escort, either daily or at frequent intervals of time. In such cases pumping plant could be installed

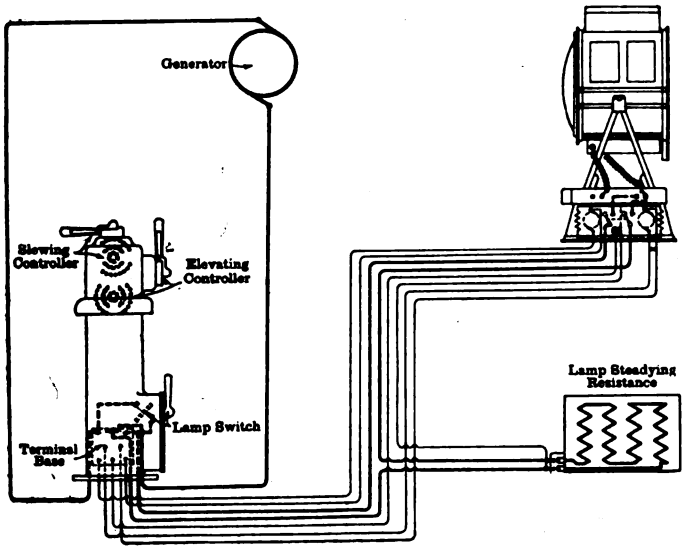

FIG. 5.—DIAGRAM OF EXTERNAL CONNECTIONS FOR ELECTRICALLY CONTROLLED PROJECTOR.

on the low ground, water supplied under pressure through small pipes, and the power transmitted by wire from a generating source. The same power, of course, would be very useful for driving the well-boring machinery which has now become a regular part of the field equipment of a modern army. It is evident, also, that the enormous increase of mechanical appliances that must be carried by the modern army demands that the means of repairing or replacing damaged parts by spare parts should be carried on at a point as near to the front as possible—in other words, that the floating workshops that now accompany our fleets at sea must be imitated on land by portable workshops forming part of the engineer's park; but the ready way in which electrical power can now be applied will enable the engineer's park to contain machine tools and thus enable repairs and renewals to be carried out in a way that was quite impossible when hand power only was available.

Although it is practically certain that great developments will take place in the direction of electric transmission of power to aid the field engineer, up to the present little has been done, mainly for the reason I have shown, that it is only since the Russo-Japanese War following on our own South African War that we have realised the very large part that electric lighting must take in field operations. As I have shown, the equipment for lighting has been very insufficiently considered, but as soon as it is considered and provided, the power and other uses which I refer to in my opening remarks are sure to receive further development.

Probably the best means of instantaneously generating the electrical energy required for field operations, whether for searchlights, incandescent lighting or transmission of power, would be by using tractors or motor waggons fitted with electrical transmission apparatus. There are several forms in use, the Thomas system being one which appears particularly suited for the purpose. The power unit, in this case an internal combustion engine, drives a generator directly coupled to its crankshaft, and the torque required to propel the machine is communicated through a motor and the Thomas system of gearing. The system is one which lends itself to ready disconnection of the generator and motor as transmission apparatus to work as one unit for generating energy for external use either for lighting purposes or for transmission of power.

In the course of the lecture a number of interesting photographs were thrown on the screen, showing the development of the searchlight from the earliest days, and especially the types used by the men of the Electrical Engineers (London Division) during the South African War. Just recently portable searchlight sets have been designed and made by Messrs. Crompton & Co. for a foreign government which embody the ideas enunciated in the above Paper. The accompanying illustrations show one or two types of modern searchlight and the way in which they can be controlled from central points.

AUTOMATIC PROTECTIVE SWITCHGEAR FOR COLLIERY SERVICE.*

BY E. B. WEDMORE.

Summary.—The author discusses the arrangement of trip coils and the discriminating action of automatic leakage devices in mines. He also refers to armouring and the earthing of the neutral point of three-phase generating plant.

In making any comparison between alternating and direct-current systems, there is an inherent difference which materially affects leakage problems. Should one pole become earthed on a direct-current system, the generating plant serves to maintain a constant, positive or negative charge on the other pole, the charge on the whole system remaining stationary. On an alternating-current system, however, owing to the repeated alternation of polarity, if one pole were to become earthed at any point, the generating plant would alternately charge and discharge the whole system through that point. This charging current serves to screen any change in the insulation resistance of the system, and on high-tension systems of any magnitude increases the risks arising from leakage. The recommendations embodied in this Paper apply principally to alternating-current systems, and the discriminating devices in particular are suitable only for alternating-current service.

On a completely insulated three-phase system, complete protection can be obtained by the use of automatic switches having tripping devices connected in two only of the three conductors. Where the mid-point of the system is earthed, a fourth conductor, namely, the earth, comes into use, and serves as a return conductor in case the insulation between one conductor and earth breaks down; therefore, in this case a tripping device is inserted in each phase, so as to obtain complete protection. This arrangement gives equal protection against overloads, faults between phases and faults to earth.

On high-tension circuits it is customary to employ current transformers to excite the trip coils; and where this is done it is possible, by a simple artifice introduced by the writer, to obtain independent control of the adjustments for operation on overloads and on leaks to earth. This consists (*see* Fig. 1) in the transfer of one trip coil

* Abstract from the "Transactions" of the Institution of Mining Engineers, by permission of the Council, of a Paper read at a meeting of the Midland Institute of Mining, Civil, and Mechanical Engineers, on December 5th last.

Digitized by Google

from the usual position into a return circuit common to the three current transformers. This coil will then be operative only on faults to earth, and the other two will take care of all overloads or faults between phases. By the use of this device independent control is obtained of the adjustments for operation on faults to earth and on overloads. For example, the overload coils at 1 and 2 may be controlled by a delaying device adjusted to operate on a sustained overload, but to prevent the switch from operating on a momentary overload. At the same time, the third trip coil may be adjusted to operate instantaneously on a leakage current of less than normal load.

Mr. Robert Nelson's suggestion * consisted substantially in the provision of devices capable of automatically disconnecting feeders in case of a small leak. By the use of a sensitive relay at point 3, the protection required is obtained without the use of the special transformer, carrying all three conductors, previously suggested for this service. Where a sensitive relay is employed, it is necessary to

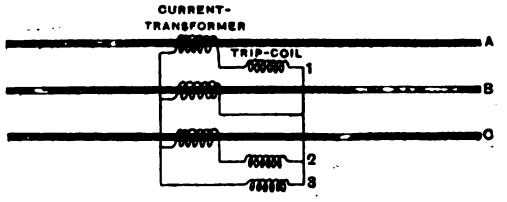

FIG. 1.

ensure similarity of the three current transformers, as otherwise, say, on a momentary overload, a current would flow in the relay, representing a spurious leak. This current, due to internal differences, is kept within limits by using a form of overload device which normally makes no demand on the current transformer. This takes the form of a trip-coil shunted by a low resistance fuse (Fig. 2). Where relays are employed, the oil switches are operated by trip coils excited off any convenient source of supply, preferably independent of the alternating-current supply, such, for instance, as the exciter circuits or a small battery. Where individual motor or other circuits are furnished with a low-voltage release, this may be utilised for the purpose, the relay short-circuiting the winding; and a current limiting resistance is used in series, as shown in Fig. 3. When installed in this way, the use of leakage devices involves a minimum of addition to the usual equipment. The current transformers provided for the usual instrument equipment serve also for the automatics, and the relays—only one of which is required on each three-phase main—are the principal addition.

Should such a device be installed on any feeder, any leak to earth, not only in that feeder, but in any distributing circuit fed by that feeder, will be effective in cutting off the supply. It may be argued that, in the case of a bad "fall" the immediate disconnection of electric supply from that part of the mine is justified; but such a course cannot be contemplated in case of a leak developing, say, on the terminal board of a small motor. The writer proposes to overcome this difficulty by the use of leakage devices in series. To render this arrangement effective, some discriminating arrangement is necessary, as a leak on any one motor will affect all the devices in series, right back to the generating plant. This may be obtained

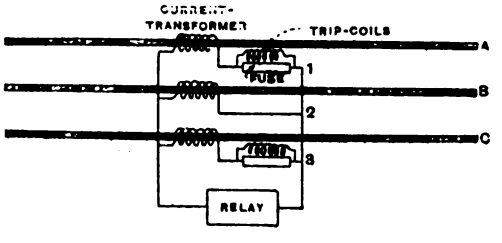

FIG. 2.

by grading the settings of the leakage devices, using a fine setting for individual motors, a heavier setting for branch circuits, and a still heavier setting for the main feeder. In the rare event of a heavy fall or other accident causing sudden and extensive damage to a cable or other device, one cannot guarantee discriminating action. Tests have shown, however, that discriminating action can be obtained in some measure in the majority of instances of severe damage, even on high-tension systems; whilst on systems of medium voltage the shut-down is confined to the damaged circuit in nearly every instance.

The author next gives particulars of various tests carried out on some cables supplied by Messrs. Callender's Cable & Construction Co., Mr. R. Nelson (H.M. Electrical Inspector of Mines) being present at some of the tests. The cables were laid on a hard foundation of iron blocks, and in some instances were deliberately placed across the sharp corners of the blocks. Damage was caused in three ways:—(*a*) By dropping on to the cable, from a height, a 15 cwt. pug intended for breaking up heavy castings; (*b*) by repeated blows with a heavy hammer; (*c*) by the use of a blunt cutting tool, driven home with a heavy hammer. These tests show the rapidity with which the relays operate and their ability to discriminate with only a small difference in the settings.

Next, as to the important question of reduction of risks from explosion and fire, a number of comparative tests have been made, firstly with leakage relays in use, and, secondly, without such relays. In order that fire and smoke might issue, it was found necessary to

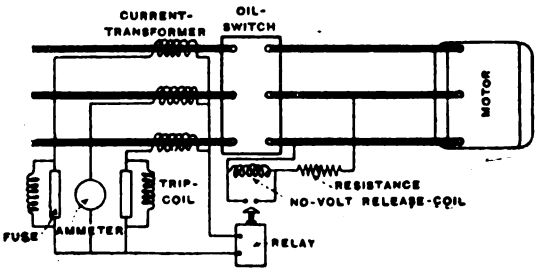

FIG. 3.

damage the cable very severely, and the most effective means proved to be successive blows of a heavy hammer. When the relays were not in use, smoke and flame issued in several instances; but in no case was it possible to produce any sign of flame, or even of smoke, when the relays were in service. The arcing would have been more marked, especially in the case of the 500 volt cable, if the branch circuit had been protected by common series fuses having a time-limit three or four times as great on a given overload as those employed in shunt to the trip coils. By a converse argument it

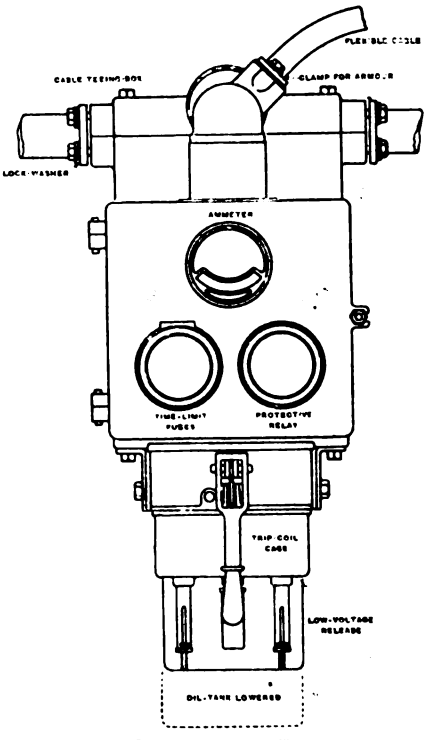

FIG. 4.—FRONT ELEVATION OF GATE-END SWITCH.

might be thought that if over-load devices giving a much shorter time limit had been employed, the same immunity from fire would have been obtained as was obtained with the relays. There is ground for this conclusion only in the case of very severe damage causing a rapid rise of current; but by the use of such devices all faults would have to develop into heavy faults before they could be dealt with, and would lead to failure of supply on momentary heavy overloads. The dangers attending the use of electricity in mines are threefold, viz., (1) danger from shock, (2) danger from fire, and (3) danger from explosion. Leakage is in all these the principal contributory cause. Danger may be reduced to a minimum if armoured cables be employed, whereby all live parts are enclosed throughout, from the main switchboard to the individual motors, by a continuous metallic covering well earthed. Every switch,

LIBRARY OF THE UNIVERSITY OF CALIFORNIA

motor, or other device, should be ironclad and provided with substantial fittings for making mechanically and electrically sound connections between the metallic cases and the metallic armouring on the cables. Fig. 4, for example, shows a typical joint between the cable armouring and a metallic case in which the armouring is firmly held under a solid metal clamping plate. This joint, if made with lock washers under the nuts, will never come loose. Several types of flexible cables suitable for this system are obtainable with metallic armouring. If this system be employed and efficiently carried out with apparatus and material designed for the purpose, all leakage currents will be confined to the metallic covering, thus removing all risks except those arising from actual rupture of, or severe arcing in, the cable. If automatic leakage devices be employed, the danger arising from these risks also is reduced to a minimum.

It is true that where the earthed neutral system is employed the majority of defects will result in leaks which will cause the automatics to operate before the fault can be discovered by other means and the faulty portion isolated. Where, however, discriminating devices are employed, and especially devices such as the leakage devices advocated by the writer, the electric supply should not be disturbed except at and beyond the point where the defect exists.

In the past where the neutral has been earthed, it has been necessary to employ a connection capable of passing sufficient current to operate the overload device with the heaviest setting on the largest feeder. Where there are but few main feeders this involves every fault developing into a heavy load on the system before the automatics operate; and should only a portion of the generating plant be running, a fault in a main feeder amounts to a short-circuit on the system. Where leakage relays are employed, however, it is possible to employ a resistance in the earth connection, which limits the leakage current under the severest conditions to a fraction of normal load. Such a connection will not prevent the operation of the leakage devices with certainty, and will serve under normal conditions to hold the mid-point of the system at earth potential; neither will it interfere with the function of the earth connection in preventing the development of small static disturbances.

The use of the armoured system with the neutral earthed ensures every defect receiving prompt attention, as every defective portion is promptly isolated and put out of service; and this tends to ensure efficient supervision, inspection, and maintenance.

Another objection urged has been that there is greater risk of shock from touching live metal where the mid-point is earthed, the idea being that the potential at the point touched is reduced to earth potential through the operator's body if the whole system is insulated. Where continuous metallic protection is provided, there is little opportunity of coming into contact with live metal. In any case, the added safety resulting from not earthing the mid-point is negligible except on the smallest systems, as the charging current of the whole system has to pass through the body of the operator before the potential is reduced.

The consideration of automatic devices necessarily involves the discussion in detail of all kinds of trouble and sources of weakness. This tends to produce a false impression of insecurity, unless the arguments are carefully followed and due weight given to the comparative infrequency of occurrence of many of the abnormal conditions dealt with. The purchase of good material and appliances is undoubtedly the surest way of automatically reducing danger and controlling continuity of supply, and amongst the latter may well be included appliances designed to meet the risks peculiar to the mining industry.

ELECTRIC BRAKING ON THE GLASGOW CORPORATION TRAMWAYS.

The following is an abstract of the discussion which took place at a meeting of the Glasgow local section of the Institution of Electrical Engineers when Mr. A. Gerrard read his Paper on this subject. An abstract of this Paper appeared in our issue of April 8th, and of the discussion when this Paper was read in London in our issue of April 15th.

Mr. J. Ferguson (chief engineer, Glasgow Corpn. tramways) said he knew that the experiments were carried over a lengthy period in all conditions of weather and track, and the results obtained were valuable. He thought the following were some reasons for not adopting electric brakes:—(1) Rapid application caused skidding; (2) frequent use at all speeds sent up maintenance charges; (3) their safety depended upon the controller contacts, which were liable to get out of order; and (4) electric brakes could only be usefully applied on a running car—*i.e.*, they could only be tested under running conditions. With regard to the solenoid control advocated, he thought the first two objections were removed, and he anticipated the maintenance cost would also be reduced. The low voltages and current with solenoid control would also be beneficial to the equipment. The absence of skidding was highly appreciated by the motormen. The Paper did not claim to remove objections (3) and (4). Regarding the disadvantage due to contacts likely to get out of order with dust or dirt, &c., he mentioned that his department now regarded this fault as a minor one, for the following reasons:—During a day's run of 120 miles they had ascertained that there was almost one application of the brake per mile per car. There were 600 cars on an average running per day. That meant there would be about 18,000,000 applications of the electric brake per annum. For the year 1909, in the "defect" reports received, only 17 were for defective electric brakes, a truly satisfactory result.

Mr. W. McWhirter thought that thanks were also due to the Glasgow Tramways Committee, as it was most unusual to find a Corporation (except on the Continent) making public any experiment like this. He asked Mr. Gerrard for the cross-section of the magnets. No doubt the length of core caused the weak pull. According to the curve shown, the magnet appeared saturated. The magnet had far too little iron in it, as with 5 amperes there was 50 per cent. more pull than at 40 amperes in the older make. In type 26C the pull was doubled. In type 25B he thought the magnets too powerful. They were very unstable on the straight part of the curve, and he was sure this would be very marked. Referring to the enormous rise in voltage, he thought the design of the traction motors contained too much iron. Experiments showed the magnetisation of these to be low down on the curve. No doubt, of course, the motors were designed for traction purposes only, and not for braking effects. The application of the solenoid control would shunt the field magnetisation and thus reduce the tendency for the voltage to rise. This was quite a good arrangement, and he thought it had come to stay. Regarding the pull, he mentioned that from experiments he had found it possible to get 160 lb. per square inch tractive effort.

Mr. Maxwell (Electric Control, Ltd.) thought the most important point was not touched on, namely, the usefulness at low speeds. The combination resorted to in Glasgow of both hand and electric brakes was, he thought, not good practice. He thought the car should have a lower schedule speed. In speaking with Mr. Dalrymple recently on brakes, the latter said air brakes required more room than it was possible to give on the single truck cars at present in use, while double trucks or double bogies were too long and not suitable for turning the corners. The schedule speed was, he believed, 6 miles per hour on the average. He instanced that American practice was to have four 30 B.H.P. motors per car and air braking.

Prof. Bailey (Edinburgh) confined his remarks more to the surging effect referred to. He imagined some was due to the electromagnets being sluggish. If an air-gap were introduced in the track magnetic circuit it would, he anticipated, accelerate the magnets coming off and reduce the surging. He agreed with Mr. McWhirter that there was too much iron in the motors. At 4 miles per hour he presumed there would only be 2 or 3 amperes for solenoids, but he did not think that was a point against it.

Mr. Sam. Mavor asked for the contact sectional area of the magnet.

Councillor Hoey (member of the Glasgow Tramways Committee) thought the Paper was an excellent and huge advertisement for the Westinghouse Co. He advised the officials to devote more time to finding out what could be done, not on what was being done.

Mr. Robertson, who was interested in railway brakes, asked Mr. Gerrard if he did not find that the 25B type solenoid would lift the car off the tracks and cause the surging referred to, and also if the 1908 type was still in use.

Mr. Geo. Stevenson asked for particulars of the cost and life of the brake shoes. Also, as the approximate miles per hour was given to three decimals, what sort of stop watch was used?

Mr. Gerrard, in reply, said the area of core in the old type of brake was 3 in. diameter, and in the new 26C 5 to 6 sq in. The shoe area in the old type was 23 sq. in., in the new small type 23 sq. in., and in the new large type 26 sq.in. He found the small new type was the best for coasting. He agreed with Prof. Bailey's remarks that the large magnet was sluggish. There was an excess of iron in the traction motors, but they were not designed as everyone knew for electric braking purposes, as this system of braking was unheard of 15 years ago. He had been requested to curtail the length of the Paper; however, he could assure them that solenoid braking was as good at 2 miles as at 18 miles per hour. The hand brake was seldom used, as it was found that the electric brake was quite good and efficient, and experiments proved that the latter was better at 3 miles per hour than the hand brake. It was found that the freedom from accidents with electric brakes was such that they were not warranted in equipping the cars with air brakes; a step which would only increase the weight of the cars without giving additional security, as accidents were not unknown with air brakes. The surging referred to was principally due to badly trimmed brake shoes. Solenoid shoes, of course, would reduce this. There was no air-gap in the magnet circuit. The large magnet was sluggish, but the practice was to put in even three magnets. Regarding Councillor Hoey's remarks, he could assure him they had come to the last word in electric braking, but with regard to advertisement he might say that both the Glasgow Tramways Department and the British Westinghouse Co. had spent money in making the experiments, and any advertisement therefrom could hardly be eliminated. The 1908 design was not now used. He could not say anything as to costs, except that it was anticipated that the running and maintenance costs would be very much reduced, the armatures not being subject to such severe service.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By C. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. B. Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861—1878).
Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial, Publishing and Printing Offices,
1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON
(ONLY ADDRESS.)
Tel.: Holborn 6363 (Two Lines). *Tels.*: ELECTRICIAN NEWSPAPER LONDON.

All Letters relating to Subscriptions, Advertisements and other business matters to be addressed Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-st., London. Cheques and P.O.s to be crossed* "Coutts & Co."
All Editorial communications to be addressed to THE EDITOR. *Letters for insertion in* "THE ELECTRICIAN," *or containing questions, to be accompanied by name and address of the writer as evidence of good faith. No notice is taken of anonymous communications.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-eighth issue of the Supplement was published (Gratis) with the last number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,085 pages), bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

PHOTOMETRIC UNITS.

When asked what sort of person an archdeacon was, DISRAELI said that he was a man who performed archdiaconal functions. In the same way, he would probably have said that a candle-power was the power of a candle, and a horse-power the power of a horse. He may very possibly have been right about the ecclesiastic; but the candle-power and horse-power are not to be disposed of in the same easy manner. The candle and the horse were probably the best things of their kind in the worlds of lighting and traction a hundred years ago; but now they seem rather out of date, and are not to be taken very seriously as scientific units.

Confining our attention to the candle, the English unit is a sperm candle, six of which weigh a pound, and which burns 120 grains of wax in an hour. Other countries have different standards, and the usual practice everywhere is to refer to some sort of primary flame standard, such as the Pentane, Carcel, or Hefner lamp. About a year ago a serious effort was made to free the matter from the bewildering confusion into which it had sunk, and to agree on an international unit for the expression of candle-power. The authorities in Great Britain, France and the United States agreed to adopt the same arbitrary unit, and this was certainly a great step forward. It involved practically no

Digitized by Google

alteration of the standard adopted in England and France, seeing that the English candle was almost exactly the same as the "bougie décimale" in France. But the American standard (which had not been so completely defined as that in other countries) had to be lowered by 1·6 per cent., and this was done on the understanding that the three countries would unite in keeping the unit constant, and would call it the International candle. As a matter of fact, it is evident there has never been any great difference between the three standards adopted by these countries, and it merely needed, as one would have thought, half an hour's talk to settle the matter. But the immense inertia that had to be overcome is probably only understood by those who have had to do with International Commissions, and, even now, Germany remains outside the scope of any real agreement.

It must be admitted to have been extremely unsatisfactory that no common standard could have been found that was agreeable to all parties. The most that could be done was to agree that 1 Hefner candle-power is equal to 0·9 English candle-power; or in other words, Germany and England interpret the words "candle-power" in two different senses. From the scientific point of view, this difference is a matter of little importance, and it is easy to correct and allow for it. And, after all, it is absurd to suppose that photometry will ever be one of the exact sciences, except to the very few. This may sound heretical, but it is none the less true. Every observer has his own peculiarities; the only thing that can be said with certainty is that the personal equation tends to disappear if the number of observers is very great. The colour of the light is also a disturbing factor, the colour of the primary standards being mostly reddish, whereas that of other sources of light may have a tendency in some other direction, which can only be neutralised by artifice. Experience in the observer is only a form of artifice, by means of which the brain adjusts itself through certain trickery to compare things that are intrinsically different. Moreover, the primary standards are themselves liable to vary with the amount of atmospheric moisture, or pressure, or with the quantity of carbonic acid present in the air. With all these independent variables, exact results cannot, as a rule, be expected. Yet International Commissions have almost always confined themselves to the scientific aspect of the matter, and, seeing that no standard lamp has been found to be perfect, the expression "candle-power," which is the only thing that interests the commercial world, has been left to shift for itself.

Wherefore, seeing that at best only an approximation is to be attained, it seems impossible to suppose that a truly international agreement, on a commercial basis, as to the meaning of "candle-power" is out of the question. Might not the Institution of Electrical Engineers make friendly overtures to the Elektrotechnische Verein, with a view to the suggestion that in future German lamps should be rated according to their International candle-power, on the assumption that 1·11 Hefner candle-power is equal to 1 International candle-power? This proposal would not interfere in any way with the use of the Hefner lamp as a standard, which is an excellent one of its kind, though it would certainly be preferable to adjust it to an international value. We do not know what objections the world of commerce in Germany, as distinct from the world of science, would be likely to raise. Possibly the position is hedged in with legal considerations. But it is expressly proposed to call the new unit the International candle-power, and therefore it is evidently different from the Hefner candle-power, or from any other candle-power to which the jurists might conceivably pin their faith.

The cynic might reply to all this that the uncertainty prevailing is such that it cannot be removed by any such step as this. The rating of an incandescent lamp at 16 c.p. is notoriously only the roughest approximation; and it is not so many years ago that arc lamps fell nominally under two headings—viz., those that gave 2,000 c.p., and those that only gave 1,000 c.p., the actual candle-power being neither of these values. An incandescent lamp is usually rated according to its horizontal candle-power in some direction, or according to its mean horizontal candle-power. In an arc lamp, the mean hemispherical candle-power is taken, while its light is never steady for a second at a time, and it is only possible to make an approximation by some rule-of-thumb method. Still, these are minor imperfections in our system, which cannot immediately be smoothed out of the way by a stroke of the pen. It is the difference of 10 per cent. between the German ratings and those of other countries, which introduces a wholly unnecessary element of uncertainty. Would it not, we ask, be within the province of the Institution of Electrical Engineers to approach the Elektrotechnische Verein in a business-like spirit in the matter? During Dr. KAPP's year of office a specially favourable opportunity seems to present itself, as he has been at different times in intimate contact with both bodies. We think it is needless to say that the successful accomplishment of this task would be very thankfully received on all sides.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Auto-Transformer Design. By ALFD. H. AVERY. (London: E. & F. N. Spon.) Pp. 60. 3s. 6d. net.

The cost of electrical apparatus of almost every kind depends in a very great measure upon the magnetic qualities of the best iron, and the conductivity of the best copper. The slightest reduction in the iron losses or increase in the copper conductivity means in many cases a relatively great saving in material. Thus when some years since, the so-called alloyed iron was introduced with not much over half the hysteresis loss and negligible eddy current loss, it became possible to work at greatly increased flux density with the same core loss. But in small transformers, the design of which was controlled by the no-load loss and not by heating, the increased output due to working at higher flux-values meant higher permissible losses; so that, instead of working at, say, 30 per cent. higher flux density to get the old loss, one could work at 50 per cent. or 60 per cent. higher flux density, and 20 to 50 per cent. higher current density, and still get the same percentage no-load loss and full load efficiency. The output for a given size of small transformer could thus be nearly twice as much as before for the same efficiency, or, say, 50 per cent. above the old output with an increased efficiency. Then when the metal filament

Digitized by Google

lamp came, and with it the demand for small house transformers, it was not only possible to provide these transformers at a smaller cost, but with less no-load loss and a higher efficiency than was formerly possible.

In the book before us, Mr. Avery deals first of all with the very great saving in material arising from the use of auto-transformer connections as compared with those of two-winding transformers, and with the advantages of balancer transformers when they can be employed. After discussing the economy of metal filament lamps he proceeds to the elementary principles underlying transformer design.

It would be easy to criticise the book in many particulars. The author, while not directly advising it, talks of cutting out the pieces of iron, which form the core, by hand, and truing them with a file (p. 44). He talks of the energy taken from the mains by a true wattless current, although he explains that such current is useless for practical purpose (p. 40). Among other things he repeats the common statement that it is necessary to insulate the corner bolts of cores to avoid eddy current loss. Is insulation really needed? So long as such bolts are symmetrically placed with regard to the flux there ought to be no appreciable eddy current loss in the bolts.

The author gives a complete account of the building of core, coils and case of one type of transformer.

Possibly the book may be a little disappointing to the actual transformer designer, but it is intended also for the user and the contractor, to whom it should prove very useful with its excellent photographs and good tables. D. K. M.

Uber Elektronen. By Dr. W. Wien. 2nd edition. (Leipzig: B. G. Teubner.) Pp. 39. M.1·40.

The progress accomplished since 1905 has not led to any revolution in the original conception of the electron theory, and the distinguished Würzburg physicist has been able to bring his original lecture up-to-date by adding a number of valuable notes. The most important recent development is the exact formulation of the principle of relativity, chiefly by Einstein and Minkowski. This principle, which renounces all possibility of discovering absolute motion, introduces some very novel conceptions of mass, space, time and force. But it has the advantage of throwing a bridge between ordinary and electromagnetic mechanics, and it is, moreover, strongly supported by the recent experiments of Bucherer and Hupak. The little work before us, though not by any means exhaustive, even as regards the enumeration of the departments of physics to which the electron theory has been usefully applied, is a lucid and more or less popular survey of many of its more important results. E. E. F.

Examination Questions in Electrical Engineering set by the City and Guilds Institute, 1900—1908. (London: S. Rentell & Co.) Pp. 95. 1s. net.

In this little book are given questions set in the three grades of the City and Guilds examinations in electrical engineering. To many of these questions, involving numerical solutions, the answers are given, and in the case of the papers set in 1908 all the questions are very completely worked out. We do not profess to have read all the answers, but those at which we have glanced appear to be to the point, the only exception being one in which the loss in a transmission line 2 miles in length is given as 97·67442 H.P.—surely an undesirable degree of accuracy. We do not doubt that the book will prove useful to teachers, not merely from the cramming point of view, but also in helping them to select suitable problems with a minimum of trouble.

RECENT PHYSICAL RESEARCH.

POSITIVE ELECTRICITY

BY D. OWEN.

As Helmholtz and Maxwell independently remarked, Faraday's Laws of Electrolysis point to the conclusion that atoms of electricity exist just as surely as do atoms of matter. In liquids the ratio e/m of charge to mass is known to vary with the chemical nature of the ion, being least (nearly 10^4 E.M. units of electricity per gramme) in the case of hydrogen. The carriers of negative electricity in liquids are never less than atomic in size. In gases, on the other hand, during the passage of a current, we now know that there are present negatively charged particles of mass far smaller, namely, $\frac{1}{1700}$ part of the mass of the H atom. Moreover, these particles are the same no matter what the gaseous molecule from which they are extracted. Furthermore, the mass of these negative particles appears to be purely electrical in origin; for it is found by experiment to increase with the speed in a way that had already been predicted in the case of motion of a purely electric charge. Again, the effect of a magnetic field on the light emitted by a gas (the Zeeman effect) is evidence of the presence of negatively charged particles associated with the light-giving molecules; and exact measurements establish very conclusively the identity of these particles with those found in the electric discharge in gases at low pressures. The phenomena of the conduction of electricity and of heat in metals have been correlated on the assumption of the presence of these free electrons or corpuscles within the inter-molecular spaces of the metal.

The existence of the negative electron, or corpuscle, may now be regarded as firmly established. One or more corpuscles may be abstracted from a molecule. The molecule is then said to be positively charged. What is this positively-charged residue? Is the negative the only kind of *electricity*, the rest of the molecule being *matter*? Or is there a *positive electricity*, distinct from the *matter* of the molecule? Or is the residue left on separation of the corpuscle *positive electricity*, possessing, like the negative, inertia—in fact, all the inertia—of the particle? The first and third questions are clearly one and the same. An affirmative answer would mean that the molecule was composed simply of negative and positive electricity, all the properties of the molecule, including its mass, being explicable in terms of electricity.

Accepting, then, the existence of the negative electron as proved, an important question arises as to what fraction of the mass of the molecule is due to the electrons present. Granted a sufficient number, the whole of the molecular mass might be accounted for as the electric inertia of the electrons. The number of electrons in a hydrogen atom would have to be some 1700, in a mercury atom 200 times as many, and so on. On this point an important Paper by Sir J. J. Thomson appeared in June, 1906, laying down three lines of argument, based on experimental data, all leading to the conclusion that the number of electrons in the atom is of the order of its atomic weight (H = 1). The number in a hydrogen atom would be 1, or at all events not a large multiple of 1; in the mercury atom 200, and so on. This, if granted, leads to the result that by far the greater part of the mass resides in the positively-charged residue of the atom. What, then, is the constitution of this residue? Is it composed of small units, which, like the electron, are the same for all substances? If so, what is the charge of each and its associated mass? Attempts towards the elucidation of these questions have been made mainly by examination of the mechanism of the passage of electricity through gases. These investigations show that in a vacuum tube there are rapidly moving streams of positively electrified particles, corresponding to the now well understood streams of electrons or cathode rays. These positive streams were first observed by Goldstein in 1886, being called Canal rays. They are seen streaming through a hole in the cathode in a discharge tube, their direction being perpendicular to the front surface of the cathode and away from the anode. Similar rays are

Digitized by Google

seen streaming from the cathode in the opposite direction, from cathode towards anode; these are Goldstein's K_1-rays, also since denoted by the term "retrograde rays." In all, Goldstein specifies five types of positively-charged ray in the vacuum tube. In hydrogen gas the canal and the retrograde rays—to specify the chief types—are rosy red in colour; in air they are blue. They cause metallic salts, on which they impinge, to emit the characteristic light of the metal—*e.g.*, sodium salts glow with an intense yellow light, salts of lithium with a red light, &c. When they fall on thin metallic films the film is disintegrated. Later on, in 1906, REICHENHEIM discovered the Anode rays, consisting of rapidly-moving positively-charged particles starting from the anode, one stream moving forward towards the cathode, a second stream in the opposite direction. These various streams of positively-charged particles may conveniently be grouped together under the title of POSITIVE RAYS, as suggested by Sir J. J. Thomson.

Whilst Goldstein traced the direction and apparent seat of origin of positive rays, WIEN made measurements of the ratio of charge to mass and of their velocity. The measurements disclosed the fact that the positively-charged particles concerned differ essentially from the negative electrons in having large masses of the order of the mass of the atom. In 1907 Sir J. J. THOMSON began a series of important contributions to our knowledge of these rays. Of these we will now give a brief account. The canal rays are found to possess speeds of the high value 2×10^8 cms. per sec.—that is, nearly one-hundredth the speed of light, a speed which, though enormous, is yet inferior to the speeds attainable in the cathode rays (6×10^9 cms. per sec.). The values of the e/m ratio and of the velocity are obtained from the deflections produced by the combined application of known magnetic and electric fields, the rays being received on a Willemite phosphorescent screen. The first series of experiments ("Phil. Mag.," May, 1907, and September, 1907) showed that the particles in the canal rays were of two kinds, the value of e/m for one set being 10^4, for the other $10^4/2$. The remarkable result was found that these values are the same no matter what the gas in the tube may be, whether hydrogen or oxygen, or heavy vapours like CCl_4 or $UrCl_4$. They are seen to be the same as for the atom and the molecule, respectively, of hydrogen, if we suppose that the charge carried is the same in each case as that carried by the H atom in the electrolysis of liquids. Careful and prolonged experiments confirm the fact that these values are found when special means are taken to exclude hydrogen from the tube. Or, to reverse the procedure, starting with a gas entirely free from hydrogen, it appears that the gradual introduction of hydrogen does not affect the character of the phosphorescence produced by the deflected beam. If, for example, oxygen be used, there are no particles present whose e/m ratio equals $10^4/16$ or $10^4/32$—that is, involving an atom or molecule of oxygen. The retrograde rays by a similar examination appear to be of one kind only—namely, positively-charged particles having the same speed (2×10^8 cms. per sec.) as the canal ray particles, but with the larger value of e/m—that is, 10^4.

It should be remarked that there are positive rays of much slower speed which possess values of e/m which are characteristic of each gases, 10^4 for H, $10^4/16$ for O, &c., which, therefore, correspond to positively-charged molecules of those gases. It is only in the case of the high-speed particles that the high value of 10^4, independent of the nature of the gas in the tube, is found. It will be seen that the results for high-speed rays strikingly resemble those now familiar in the case of the cathode rays. Sir J. J. Thomson puts forward the view that we have here proof of the existence of a definite *unit of positive electricity*, which can, like the corpuscle, be detached from the molecule.

The more recent Papers of Sir J. J. Thomson are largely concerned with the manner of production of the positive unit from the molecule. One striking experimental result is that the kinetic energy of each particle in the rays is many times greater than the work that would be done upon it in virtue of its fall down the electric field in the tube. This velocity is practically independent of the fall of potential across the tube. A total fall of 3,000 volts produces the velocity 2×10^8 cms. per sec., which a simple calculation—equating Ve to $\frac{1}{2} mv^2$—shows to correspond to a potential drop of 20,000 volts. The view is therefore taken that a molecule of gas in the discharge tube receives energy from the collisions with it of the cathode ray particles. This energy the molecule accumulates until the point of explosion is reached, when a "neutral doublet," composed of one unit of positive electricity and a corpuscle, is shot out at high speed.

The canal and retrograde rays are on this view regarded as consisting, at their inception, of neutral doublets. Their high speed renders them comparable with the particles of a gas at very high temperature, say, some hundreds of thousands of degrees Centigrade. Dissociation may take place, resulting in the production of particles of free positive and negative electricity respectively. These in their turn may re-combine to a neutral doublet; or the neutral doublet may unite with a corpuscle to form a negatively-charged particle of mass practically unaltered, since the mass of the corpuscle is almost negligible. The canal and retrograde rays would thus be composed of charged particles, negative as well as positive, whose e/m ratio is 10^4, and of neutral doublets. The experimental observations are in agreement with these conclusions, which are further confirmed by later experiments of considerable interest, which may be briefly described. A beam of canal rays is subjected to two magnetic fields in succession, their directions being perpendicular to each other and to the direction of the rays. The first field may be placed near the cathode, the second further along the beam, which goes on and impinges upon the usual phosphorescent screen. The effects on the screen may be represented as in Figs (*a*), (*b*) and (*c*).

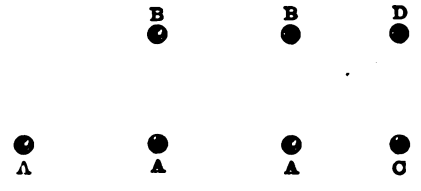

FIG. (*a*). FIG. (*b*). FIG. (*c*).

A of Fig. (*a*) represents the bright spot on the screen before either magnetic field is on. Fig. (*b*) represents the effect of switching on the first field. Two spots are now seen, one at A in the undisturbed position, the other at B, whose deflection corresponds to the ratio $\frac{e}{m} = 10^4$. Clearly the spot A is produced by rays unaffected by the field, therefore presumably uncharged while passing through it. Fig. (*c*) represents the effect when both fields are on. The undeflected spot A is still seen, corresponding to particles that have remained uncharged in their path through it. A new spot appears at C, showing deflection by the second field of particles which have acquired their charge since leaving the first field. A spot still persists at B, proving that particles which were charged in their passage through the first field have lost their charge in the space intervening between the two fields. The spot at D is due to particles which have kept their charge from the first field to the second. The equality of the deflections AC and BD proves the equality of speed and e/m ratio of the two sets of particles concerned. Here we have simple evidence of the dissociation and re-association of oppositely-charged particles, which, on the view here considered, are the units of positive electricity, and corpuscles, respectively. The "neutral doublet" has been invoked also in the explanation of the mechanism of ionisation in gases at higher pressures under the influence of X-rays, &c. The experiments of Wellisch (July, 1909) show that the velocity of positive ions in a mixture of a heavy gas, say CCl_4, with hydrogen, is practically the same as that of a charged hydrogen molecule, though the direct dissociating effect of the ionising agent is almost solely confined to the heavier molecules. It is considered impossible that the large molecule, minus a corpuscle, could transfer its positive charge to the smaller one, as an increase in potential energy would be

Digitized by Google

involved. The results are in harmony with the view that the act of ionisation consists in the ejection from the molecule of a Thomson neutral doublet, which breaks up into the positive unit of electricity and a corpuscle, these then uniting with the molecules present in the gas to form the moving ions.

This account of the views held by Sir J. J. Thomson cannot be said to give a very clear perception of the nature of the positive unit. The high-speed positive particles in the vacuum tube are independent of the gas whence they are produced. The ratio of charge to mass is known, but not the absolute value of either. Whether the value of the charge of the positive unit is equal to that of the negative electron is not determined. The ratio e/m is the same as for a H atom in the electrolysis of acidulated water. Does this mean that a hydrogen molecule is composed of two units of positive electricity and two corpuscles? Again, if the preliminary to ionisation of the molecule is extrusion of a fundamental constituent of all molecules, namely, the neutral doublet, with subsequent decomposition of the latter, one would expect to find positive particles of $e/m = 10^4$ amongst the rays emitted by radio-active bodies. Prof. Rutherford's remarkable series of experiments on the α particle prove that this body is a positively charged atom of *helium*; thus we have a mass about four times as great as that of the hydrogen atom, although the velocity of the particle (10^9 cms. per sec.) is many times greater than that of the high-speed positive rays in the vacuum tube.

In conclusion, other lines of experimental research which have a bearing on the question of the existence of a free positive unit of electricity may be touched upon. It is well known that the Hall phenomenon varies in sign in different metals. The same remark appears to be true of the Zeeman effect. This effect of a magnetic field on the period of vibration in line spectra has been explained satisfactorily in terms of the electron, the e/m ratio deduced from the observed displacement of the lines working out to be equal to that obtained in experiments in the gas discharge tube and on the β-rays emitted by radio-active bodies. Jean Becquerel (1909) has shown that the Zeeman effect applies also in the case of the absorption bands of some crystalline bodies and their solutions. Furthermore, he records that he has observed a reversal of sign; that the sign of the accelerated circularly polarised component, as viewed *along* the direction of the magnetic field, is in some cases opposite to that hitherto observed. This result is confirmed by Dufour in the case of certain gaseous emission spectra. In the previous year Prof. R. W. Wood had discovered a *positive* rotation in the case of some of the absorption bands produced when plane-polarised light is passed through sodium vapour in a magnetic field. If the normal effects in the above-mentioned classes of phenomena are due, as has been supposed, to the presence of negative electrons, the question arises as to whether the reversed effects are to be taken as implying the presence of positive units or positive electrons.

Mention may be made, too, of the discovery, by Stark, of Göttingen, of the Doppler effect in the light emitted by the positive rays in a vacuum tube discharge. Measurements of this effect lead to the determination of the speed of the particles emitting the light, and seem likely to contribute to our knowledge of positive electricity.

Progress along these various lines of research will be eagerly awaited in the near future.

EARTHED *VERSUS* INSULATED NEUTRALS IN COLLIERY INSTALLATIONS.

We give below an account of the discussion which took place at a meeting of the Institution of Electrical Engineers last week, when Mr. W. W. Wood read a Paper on this subject. An abstract of this Paper was given in our last issue.

Mr. J. G. Wilson said the keynote of the Paper was that each case should be considered on its merits; but, nevertheless, there was a tendency on the part of the author to lean towards an insulated neutral, or, at any rate, to avoid a general practice of earthing the neutral. In fact, the author in his conclusions stated that "generally an insulated neutral was better where permanent plant was at work and the cables were not liable to mechanical damage." The speaker thought that these qualifications rather cut down the conclusion, because there were in most cases underground portable tools supplied with electricity, and cables underground were as much as any liable to mechanical damage. The speaker advocated earthing the neutral, and further than that, whether the supply to the pit was obtained from a supply company and transformed down or whether it was generated locally, all underground cables should be armoured and the armouring should form a continuous connection both to earth and to the neutral point of the system. He doubted very much the advantage claimed by the author that the danger of shock was reduced in the case of an insulated neutral, since with an extensive supply it was impossible in practice to avoid leakages to earth, and even were it possible to do so it would not be continuously possible. Moreover, Mr. M. B. Field had authoritatively pointed out in his communication in Vol. XLI. of the "Proceedings," that even apart from earths on the different phases the tendency of the capacity effect was to keep the neutral point of the system at or about earth potential, and that insulating it was no safeguard against shock. The speaker thought, however, that what was more important than shocks was the danger from explosion by ignition of gas or coal dust underground. Assuming that the installation was a good one and that the switchgear underground was of the modern enclosed type, there was yet the possibility, over which the engineer had least control, of the roof falling on to the cable. If the latter was thoroughly armoured it should stand a great deal, but if damage did occur to the insulation it was most important that the supply should immediately be cut off, and he thought that was the gist of the whole matter. If the neutral point of the system was unearthed the supply would not be cut off unless one phase was forced in contact with another, and even then the current had to rise to a value perhaps double that of the capacity of the motors served by the cable, and considerable heating and arcing inside the cable would occur, which might result in exposing an arc. If, on the other hand, the neutral point were earthed, the supply could be cut off instantaneously either by a balanced protective system or by having the cut-out furnished with a trip coil connected in series with the sheathing of the cable. The author had well pointed out the importance of reliability of supply, and under that heading had quite rightly suggested that anything like continual cutting off of the supply by those devices would be very harassing to colliery managers. The reliability of supply was really most important in the department of winding and fans, both of which were done at bank, and neither of which, if the supply was properly arranged, need be affected by the tripping of an automatic switch in circuit with the underground cables. The temporary cutting off of the supply underground from haulage, or even pumps, while exceedingly objectionable, should not be considered where it was a question of actual danger to the mine by explosion. He thought the subject of flashing to the casing of switchgear, &c., touched on in the Paper, was really a question of design, of which it was impossible to overrate the importance, but altogether distinct from the subject of the Paper. In conclusion, he strongly advocated the earthing of the neutral in all cases of a three-phase supply to collieries.

Mr. H. W. Clothier said the author claimed for an earthed neutral that it was possible to isolate a damaged circuit, whereas with the neutral insulated the claim was that the damaged circuit was not interrupted. He thought that any system which allowed a damaged circuit to remain in use was unsatisfactory. He advocated metallic armouring from the generator to the load, and said the advantage of having thorough metallic armouring on all cables was prominent when the risks of explosions was considered. It was important to avoid flashing external to the cable. He knew of cases of falls of roof on armoured cables where the damaged circuits had been isolated automatically, and the action had been so rapid that it had been impossible to detect the place where the "short" had occurred. He did not think one could have too many earth plates in a mine. The illustrations in the Paper should not be taken too seriously as arguments against earthing the neutral. The defects shown by them could also be made to apply to insulated neutrals. The author suggested that the size of the earth wire should be large enough to carry a current which would blow the fuses of the plant. This did not give an adequate idea of the necessary dimensions of an earth wire. The cost of the system of leakage protection (originated by Mr. Price), shown in Fig. 4 of the Paper, was very little more than the ordinary overload protection. The statement about the price of armoured cables also should be corrected, as the cost of armoured cable was not double that of unarmoured cable. For small cables the difference in cost might be 40 to 50 per cent., but in larger cables it was somewhere in the neighbourhood of 20 per cent. His, the speaker's, conclusions were that (1) sound, metallic, continuous armouring should be used throughout the system, (2) for safety this must be efficiently earthed, (3) the neutral point should also be earthed, if only for the fact that by so doing a better and safer system of automatic protection was obtained. His remarks mainly referred to low-tension systems in mines, as he understood the author's Paper left no doubt as to the advisability of earthing the neutral on the high-tension circuits of power supply undertakings.

Mr. W. H. Patchell thought that the earthing of metal casings was more important than the question of whether the neutral point should be earthed of not. In his opinion the conductor should be enclosed in a metallic casing and thoroughly well earthed. He thought also that if more money was put into the skilled attention that was given to the installations less trouble would result. A good deal had been heard of faults due to falls of roof, but it was very hard to run a case to ground where there had been a flash due to a fall in a mine. He did not say that such a thing could not happen, and he thought it was for them as electrical engineers to take proper precautions to prevent an explosion from

Digitized by Google

such an occurrence when it did happen. He thought it would be a good thing if authors when quoting Papers gave the references. The remarks quoted with reference to the American Institute were not recent, and were not those of the President of the American High-Tension Committee, Mr. Mershon, but were President Scott's introductory remarks to a Paper by Mr. Blackwell some seven years ago. Whether the conditions had since changed depended rather on what earthing they were considering. The matter was again discussed by the American Institute of Electrical Engineers in 1907, when, as far as the discussion went, they practically paired for earthed and the unearthed arrangements. The bulk of the evidence was in favour of earthing the centre of a star-connected low-tension distributing system.

Mr. W. C. MOUNTAIN regarded Mr. Wood's Paper of considerable practical value, because whether the neutral should be earthed or unearthed in connection with colliery work was an entirely different problem from the high-tension schemes referred to in Mr. Patchell's remarks. In connection with colliery installations one had two main objects in view: (1) to ensure as far as possible that the lives of the men working underground should be protected by having the safest possible system; (2) that the machinery installed underground should also work with the least possible risk of breakdown. It must be remembered that in colliery installations, whilst there were isolated instances of motors being run at a voltage as high as 5,000, the ordinary voltages with which one dealt were either 650, which came within the limits of medium pressure, or 3,000, which was the maximum allowed under what was at present known as high pressure; and there was no doubt that the bulk of the work in collieries would be carried out at a pressure not exceeding 650 volts, except for larger motors in connection with heavy pumping and haulage schemes. As earthing the neutral merely limited the pressure which one would receive in getting a shock to 58 per cent. of the maximum voltage, it was quite clear that as regards safety to life nothing could be gained by earthing the neutral, even on a voltage of 650, because this would mean that any person touching a live wire when standing on the earth would still receive a shock due to a voltage of 375, which would be fatal in most cases. With the higher pressure—namely, 3,000 volts—of course the certainty of death would be greater still. Dealing with the question of mechanical breakdown he believed that certainly for all voltages up to the limit of medium pressure—*i.e.*, 650—and almost as certainly up to voltages of 3,000, there was a distinct advantage in keeping the neutral insulated, because with a proper system of earth detectors, which could be used with an insulated neutral, it was possible to detect immediately the existence of an earth and to remedy the defect as quickly as possible. He had found, after many years' experience both with continuous current and later with three-phase current, that in all collieries, due to the changes of temperature, accumulation of dirt on connections, and the fact that in some cases colliery motors did not receive the same attention as motors which could be more carefully examined in daylight, there was a great tendency (when they were subjected to a constant pressure between the frame of the machine and the conductors due to earthing the neutral) for creeping to take place which finally broke down the insulation; he, therefore believed that, except perhaps in installations where the voltage was very high and where there was a difficulty in getting the same comparative degree of insulation in the slots of the motors and on the windings as on medium pressure work, for practical reasons it was desirable not to earth the neutral. There seemed to be a great deal of confusion in the minds of men connected with the colliery trade as to what earthing really meant, and when one spoke of earthing the neutral they were liable to confuse it with earthing the machinery itself. He considered and strongly recommended that anything of a metallic nature which was liable to be touched by any of the attendants, and which contained electricity, such as the motor frame and switchgear frame, should be as permanently and absolutely earthed as possible, but in connection with earthing it required to be made clear as to how these permanent and satisfactory earths could be obtained. There was no doubt very great difficulty in many dry mines in obtaining an earth, and under such circumstances, unless one relied upon non-earthing of motor frames and the maintenance of a high perfection of insulation throughout, it became necessary to consider the armouring of cables and using the armouring as an earth return. It was also possible to lay in the ground disused haulage ropes which could be permanently earthed to the pump and connected to the frames of the motors and switchgear, and this would form a very efficient arrangement. Of course, a further alternative was to have, in the case of unarmoured cables, an earth shield on the cable itself. He knew that he was not voicing the opinion of some of the leading colliery men when he advocated this system of earthing frames in preference to the maintenance of a high degree of insulation, and he was informed quite recently that in a prominent colliery in the Midlands, where they had had 15 coal-cutters at work on a totally unarmoured system and the cutters had been running for 12 years, they had never had an accident of any kind. At one time they suffered from breakdowns of the motor coils and armatures, due to intermittent leakages, but now that they had taken precautions to ensure that any earth which might appear was immediately rectified, the coalcutters had run almost without breakdown, and they cut as much as 15,000 tons of coal with one machine without taking out the armature or making any repairs. Personally, he believed in the use of armoured cables for colliery work, at any rate where there was any liability of accident due to a fall of the roof, but there were undoubtedly many positions in a colliery, such as in travelling roads and in other places where the roof was well supported, where it was not necessary to use armouring for mechanical protection, and under such circumstances he thought it was rather hard to insist upon the use of armouring if it were merely for the purpose of being able to use a protective device, such as the Merz-Price. There was no doubt, however, that where there was any risk of the roof falling and the cables becoming damaged, armouring afforded a very great mechanical protection, and he considered that generally for colliery work armouring was to be recommended in all installations where the voltage exceeded 650. It was, however, only fair to state that in all his 22 years' experience he had never known of the severance of an armoured cable through a fall of roof, and the experiments which were conducted in connection with the previous inquiry into the use of electricity in mines showed how extremely difficult it was either seriously to damage or cut a heavily armoured cable. Assuming that armouring was adopted, it, of course, enabled a protective device to be used, and, whilst he did not wish for a single moment to depreciate the advantages of such devices when applied in suitable places, he did not think there were very many positions in a colliery—*i.e.*, an ordinary colliery installation—where such a device was required, nor would there be any advantage from its adoption. To his mind the use of apparatus of this kind, which was automatic in its action, would give an altogether false sense of security, and everyone knew if one had to depend upon automatic gear such gear had to be very constantly tested and tried to see that it was in working order; and very often when really required to work it was found to fail, therefore, he considered it was far better to rely upon thoroughly sound mechanical work, constant supervision and the use of proper earth detectors. To sum up the position finally, he thought that Mr. Wood's Paper had created a very useful discussion, and, whilst he generally agreed with the previous remarks as to the desirability of earthing the neutral in connection with high-tension central station schemes, he still felt that for colliery work, knowing all the difficulties which existed, a system with unearthed neutral carried out in a sound mechanical manner was to be preferred, and if colliery owners and those in charge of colliery installations would only insist upon their machinery and plant being properly looked after by competent men the fear of accident which existed at the present time in the minds of some people would then be entirely unwarranted.

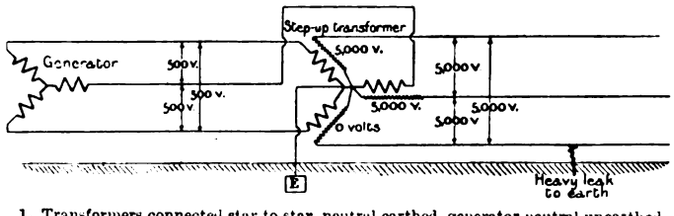
Mr. J. F. C. SNELL said that Mr. Mountain had left him unconvinced on the question of the earthing of the neutral of three-phase systems, and other speakers had rather digressed in dealing with the question of earthing on transmission lines. They were dealing with the earthing of the neutrals in colliery installations, and he was bound to say that after the very careful investigation which Mr. Patchell, he (the speaker) and a few others had to make on behalf of the Institution in connection with the new Coal Mines Regulation Acts, he felt it was imperative that the neutral of a three-phase system should be earthed, nor did it interfere in any way with the simplicity of the system. In conjunction with a complete system of armouring it seemed to him that one then obtained a thoroughly good distribution system, and one which protected the employé from danger of shock, and, what was much more important, it minimised the risk of explosion, either of gas or of coal dust. The cables, however, must be completely armoured, and he suggested that all joints should be thoroughly bonded and the frames of all fixed machines should also be bonded to the armouring, so that throughout the whole of the distribution system a completely armoured and protective system was obtained. It was a safeguard in case of faults, it entirely eliminated earthing troubles and it was a complete protection against the many dangers which occasionally arose in certain mines. On looking up the "Journal" of the American Institute of Electrical Engineers he found that the armouring of cables was usually protected by jute; but one objection raised to this was "that the miners had a habit of removing the jute from the cables and using it for kindling fires." Incidentally, they also "used oil from the transformer cases in order to re-light their lamps"! The author stated in the Paper that in places where there was no danger of accidental contact, damage from falls of roof or sets off the line, or of explosion, "armouring was an unjustifiable expense." Mr. Snell thought that by eliminating those four things the author had eliminated all the dangers that arose, and as one or other of these dangers was practically always present in collieries it seemed that armouring was justifiable and absolutely necessary. It would be a great mistake if armouring throughout were not made compulsory in collieries, otherwise patchy systems would result, and he hoped that compulsory armouring would be included in the new Regulations. He agreed with the author that the cost of maintenance was of greater importance than first cost. This was a question in which the first cost was really immaterial.

Mr. E. B. WEDMORE said that he was in entire agreement with the remarks of the last speaker. He did not agree with the author's view in regard to the statistics. If all those fatalities which occurred where electricity was not in use were struck out, the percentage would stand at a higher figure. It was their duty to reduce that figure. A detailed examination of the statistics showed that in the majority of cases the danger might have been avoided by employing the system advocated by Mr. Snell, Mr. Wilson, Mr. Clothier and other speakers. He thought that the arguments put forward by the author against earthing the neutral point were, in many cases, faulty, in that he referred to defective systems that ought never to have been employed. The illustrations in the Paper all showed systems which should not have been employed. The author seemed to suggest that it was a proper course in collieries where the neutral point of the system was insulated to operate the plant with one pole gone to earth, but the speaker thought it would need a stronger argument than love of money to justify such a course in the large majority of collieries. When one pole had gone to earth, unusual stress was thrown on the other two poles, thus finding out the weak points on those two poles, and bringing about a short-circuit. It was stated that there was need for better insulation and greater creeping distances where the neutral point was earthed. He did not know on what grounds that claim was brought forward. Cable makers had advocated greater insulation where the neutral point was insulated. The argument in regard to the

Digitized by Google

safety of operating with the neutral point earthed seemed to be largely based on the fact that if one kept the neutral point insulated one could allow the system to go to rack and ruin without any shut-down. He was certainly in favour of a continuous metallic covering, earthed at one or more points, and if that was granted then there were good arguments for the leakage devices which had been referred to as unnecessary complications. That idea had arisen from a misunderstanding as to the character of the devices advocated. In many cases discriminating action against leaks could be obtained by means he had suggested, with a corresponding simplification of the automatic devices.

Mr. H. M. Sayers was in favour of the earthed neutral. He pointed out that the earthed neutral on a three-phase system ensured a definite distribution of the potential, one advantage of which was that the designer of all the apparatus in use knew with what pressure he had to deal, and could distribute his insulation in the most economical and efficient way. Another advantage was that it provided a constant watch upon the insulation on every branch of the system, so preventing a high-resistance fault remaining undetected until an accident found it out. He thought the advantage claimed by the author that leakage to earth *probably* resulted in isolating the damaged circuit should be put more strongly. It was only a matter of proper devices to ensure that leakage was discriminated from overload current and positively ensured isolation of a damaged circuit. He challenged Mr. Wood's suggestion that under the conditions shown in Fig. 1 of the Paper (*see* diagram herewith) the mains might be subjected to the full pressure. The distribution of pressure shown on the high-tension side of the transformer was impossible. Further, under such circumstances, the pressure of the generator would undoubtedly fall considerably, and he could not understand, if there were any kind of leakage trip device on the circuit, under what conditions the first indication of anything wrong would be the arcing of a lightning arrester. He was glad to see that most of those who had taken part in the discussion were in favour of a completely armoured system and



1. Transformers connected star to star, neutral earthed, generator neutral unearthed.
2. Earth occurs on one phase and short-circuits it.
3. Voltage on short-circuited phase falls to zero, on other two rises to full-line volts, increasing stress on insulation of two phases in ratio of 58 to 100.

considered it the proper system for all fixed work. Mr Mountain had made an exception for portable apparatus. Special precautions might be taken in such cases, but there were such things as flexible armoured cables.

Mr. H. Brazil said that in regard to earthing, a point which had not been raised was whether to earth direct or through a resistance. He thought earthing through a resistance was desirable, and in the discussion on Mr. Rider's Paper had described an earthing resistance of the carbon powder type which was very suitable for that purpose. At the time referred to the resistance was more or less theoretical, but since then one had been made and was in use on a large 11,000-volt system in the north of England. This resistance allowed 200 amperes to pass to earth when a fault occurred, and if the pressure was kept on, this increased to 330 amperes in about one minute. By the use of this resistance, all the advantages of a direct earthed neutral—viz., the limiting of the rise of pressure due to surges or resonance—were obtained, without the disadvantage of an abnormally large current flowing to earth; further, the automatic cut-outs were only called upon to break the current for which they were set, instead of perhaps 10 times that amount, as might be the case with the neutral earthed direct.

Mr. C. H. Wordingham endorsed other speakers' remarks as to the safety of earthing. He thought it was rather weak-kneed in central station practice to run normally with the middle wire earthed, but to insert a resistance when a fault occurred. He, therefore, advocated direct earthing instead of through a resistance.

Mr. S. Z. de Ferranti simply wished to repeat what he had said before in regard to earthing under other circumstances—viz., he thought most emphatically that it was desirable thoroughly to earth the neutral point, and not only to earth the neutral point but also substantially to cover and enclose the whole of the parts carrying a potential high enough to do any damage.

The Chairman (Mr. S. Evershed) said he would like to add his word on the side of those who believed in earthing the neutral, and certainly on the side of those who endeavoured to enclose all parts in a metallic sheath.

Prof. D. Robertson (communicated) was of opinion that the neutral point should be earthed in every case. So far as shock was concerned an insulated system would probably be virtually earthed by the capacity of the system, seeing that the current required to produce a serious shock was so small, while any slight leak in one main would make the others more dangerous than they would be in a system with its neutral earthed. He failed to see how the author got the 16 per cent. advantage in favour of the insulated system in the matter of insulation strain. The stress between the mains was the same in both cases, and if the neutral point of the insulated system happened to be at earth potential the stresses between each and earth would also be identical in both. But if, as was more likely to be the case, one of the mains, or the apparatus connected to it, was more leaky than the others, the potential of those others would differ more from that of earth than in the earthed system, and the strain on the insulation would be greater, not less than with the latter. The best use was made of mains when they were all at equal potentials relatively to earth. The smaller liability to flash over to the metal casings with the insulated system, to which the author referred, was due to the fact that the system was very kind to its weakest part as regards insulation from earth, for it adjusted the potentials so as to throw the burden of the strain on the other mains, and no arc could be formed so long as the rest of the system was good. The fault did not cause any particular inconvenience or give any very obvious indication of its existence, and in very many cases it would be left undiscovered, or unremoved, until another developed elsewhere, when the results would be at least as bad as on the earthed system. Meanwhile the insulation had been strained by anything up to 73 per cent. above the normal. That was the great objection to unearthed systems. Mr. Wood's objection to the earthed system in Fig. 1 was not a valid one. No one who knew what he was about would allow three-phase transformers to be connected in the way shown in Fig. 1 of the Paper (*see* diagram herewith). Unless there was a fourth conductor in the primary system joining the neutral points of the generators and transformers, the primaries should always be mesh-connected, and certainly the double-star arrangement should never be used. To prevent triple frequency currents circulating between generators running in parallel with their neutrals connected could be entirely avoided by designing alternators so as to have no harmonics in their E.M.F. wave whose order was a multiple of three. It was only necessary to have six slots per pole and connect the windings so that any one and the *second* from it formed one phase, instead of connecting adjacent ones as was usual.

Mr. J. S. Peck (communicated) mentioned that the reference in the Paper to the instability of the neutral point with star to star connected transformers was correct where three separate transformers were used, or where the three-phase transformer was of the shell type or of the Berry type. Such transformers should never be connected star to star unless the neutral points of generator and transformers were earthed or were connected directly together. The delta to star connection was greatly to be preferred for transformers of the above types. With the core type three-phase transformer, the neutral might be considered stable even with the star to star connection, for a short-circuit across one phase would cause excessive currents to flow in the other phases, and so trip the breakers. With the neutral points of transformers and motor both earthed it was possible to transmit three-phase current in the event of one line conductor becoming open-circuited, while with unearthed neutrals or with the neutral at only one end of the circuit earthed, only single-phase current could be transmitted with one line conductor open-circuited. He disagreed with the author and saw no difference in the stress on the insulation whether the neutral point was earthed or not.

Mr. F. O. Hunt (communicated) said with reference to Fig. 4 of the Paper and in view of the fact that there appeared to be a tendency on the part of some engineers to regard leakage trip gear as a complete solution of the safety problem, it might be desirable to place on record some figures relating to the length of time which, by reason of the inertia of the switch parts, must elapse before the action of the trip gear could cause isolation of the faulty section. By means of an oscillograph record during a short circuit test of a turbo-alternator at a local colliery it was found that nearly three periods elapsed between "make" and "break." As the frequency was 40, that indicated a duration of about $\frac{1}{15}$ second, which would, undoubtedly, be long enough for the ignition of gas or coal-dust if they were present at the fault.

Mr. A. F. Stevenson (communicated) thought that actual contact with colliery work brought one into line with the author's summing up of the case—viz., that it was generally preferable to insulate the neutral. In the event of a motor or armoured cable failing on an earthed neutral system at a time when the plant had to be kept running and could be by removing the earth wire or bonding, the temptation was great to do so, with the result that the motor or the armouring was in a highly dangerous condition. On the introduction of leakage indicators, as ordered by the Home Office, it was found that shocks were much more severe. His experience with automatic devices was that they were only of use where the "good man" had charge of them, otherwise they would be wedged or tied up so as to stop their being a nuisance. It was in the pit where the staff was insufficient that simplicity was needed.

Mr. W. Bolton Shaw (communicated) thought the advantage lay with the earthed neutral, but it should be worked in conjunction with armoured cables and switch boxes, &c., having their casing solidly connected to the armouring, which should be earthed at the generator and so connected to the neutral. With that arrangement a leakage to earth almost always developed at once into a "short," and brought out the circuit-breaker, thus isolating and at the same time locating the faulty circuit. He considered that the risk of fire from a momentary short-circuit, especially when confined within an earthed envelope, was very much less than from a continued leakage. The opening of the circuit as the result of a leakage had three great practical advantages over a mere indication on a leakage indicator. It stopped the trouble at once, it showed on which circuit it was and it prevented the circuit from being worked with the fault still on. Regarding shock, he thought that the advantages claimed by the author for the insulated neutral seldom existed under ordinary working conditions on an installation of any considerable size. There was always a certain amount of leakage on the system from phase to phase via earth, and that was recognised by the present Home Office rules, which permitted a leakage current of $\frac{1}{1000}$ of the maximum supply current. The leakage indicator did not indicate the amount of that leakage, but only showed whether it was out of balance. If it was not much out of balance, the neutral point would be

Digitized by Google

very little different from earth potential. A person coming in contact with any one-phase merely shunted a portion of the leakage on that phase, and unless the leakage was extremely small the effect on the P.D. between that phase and earth would be slight. The voltage of the shock he received would, therefore, be practically the same as in the case of a system with earthed neutral. The danger from the flash due to a "short" was minimised in the case of switches, &c., by the flame or gas-tight cases required by the electricity rules. He was strongly in favour of using paper lead-covered armoured cables wherever practicable. With that type of cable he had had very heavy "shorts" occur without showing any signs outside the lead covering. Armouring did, no doubt, add to the cost of cables, but it had the great advantage of providing a substantial and visible earthed conductor to which all frames and covering could be connected. It also added greatly to the durability and mechanical strength of the cable, and the latter could be moved from one road to another—as was often necessary—with much less risk of damage than unarmoured cable. The sine of earth wires, he thought, should also be determined with a view to plenty of mechanical strength, and it was also advisable to have them stranded. With transmission lines having an earthed neutral and carried on iron posts it might be advisable to connect all the posts together by an earth wire, which could be fixed above the line wires and so serve as a lightning guard. The reason he suggested that was because he had known a line wire break away from an insulator and fall on the cross arm, which was iron as well as the post. The post was set in the ground without concrete, but had attached to its lower end anchor or fin plates of considerable area giving a reasonably good earth contact. The voltage of the line was 3,300, but the resulting fault was not sufficient to trip the overload circuit-breaker which was set for about 80 amperes. He found on measuring the earth resistance between two adjacent posts which were 56 yds. apart that it amounted to about 40 ohms, and was practically the same between posts three spans apart, so that between the neutral earth and any post the resistance would be above 20 ohms. In addition to this the neutral was earthed through a 12 ohm grid resistance. He did not think a resistance in the earth connection to the neutral of a high-tension system served any useful purpose. The argument that it prevented an excessive current when a short to earth occurred seemed to him to be against rather than for it. In any case, a "short" between phases produced a much larger current, and there was no serious difficulty in coping with it. As to earthing the neutral with generators running in parallel, he had found the system of having the neutral of only one generator switched on to the earth bar at a time to work perfectly satisfactorily. There was a rather curious effect produced where generators were paralleled by a bank of lamps cross-connected direct on to the 'bus bars. If the incoming generator was run up with its neutral earthed as well as that of the running machine, the lamps showed an intermediate bright point first on one set and then on the other between the in and out of phase positions. That might be mistaken for the "in phase" position and lead to the machine being switched in at 120 deg. out of phase.

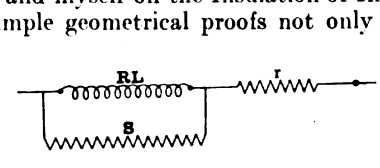
Mr. W. W. Wood, in reply, said he was glad to see that several of those more intimately connected with mining work agreed that it was desirable to lay down no hard-and-fast rule as to whether the neutral should be earthed or insulated. Among those who were in favour of earthing the neutral under any circumstances, there seemed to be rather a tendency to regard the question from the point of view of the high-tension central station of large size; but, of course, there was a good deal of difference between the conditions governing the running of such a station and many colliery plants. In the case of the latter, although it might be very inconvenient to stop during a shift, it was nearly always possible to arrange that any underground plant could be shut down at a few hours' notice (*i.e.*, at the end of the shift) without inconvenience, and it was often of considerable importance to keep the plant going for a few hours. With regard to one speaker's suggestion that as long as the winding and fans could be kept going it did not matter about stopping haulage or other plant, he appeared to have overlooked the fact that if the main haulage were stopped the only thing left to wind would be the men. The advocates of the earthed neutral had not put forward any very powerful arguments in its favour, but seemed to have devoted their attention to proving that it was just as likely that one would get a shock on an insulated system (1) on account of the natural tendency of the neutral position to be fixed, as shown by Mr. Highfield, and (2) on account of the fact that there must be some slight leakage on other parts of the system. This was, of course, regarding the matter from the point of shock alone, and disregarding the question of reliability of supply. Replying to these two points, however, (1) While a shock due to capacity effect could be received on an alternating-current system through making contact with one phase and earth alone, the current which could flow could not exceed the charging current, and was not likely to be as great as that. In a very large or high-tension system this charging current might be sufficient to produce fatal results, but on many 600-volt colliery installations at, say, 40 or 50 cycles, the charging current was quite small. (2) While on even a completely insulated system there must be leakage, on a 500-volt system of medium size this leakage (if the installation were kept in good order) was so small that while it would be quite sufficient to deter anyone in making a practice of treating live terminals with contempt, it would be very unlikely to produce fatal results. In any case it was obvious that there was more chance of surviving shock if it was received where the neutral was insulated. As the first object of either system was to secure the safety of those working underground, it would seem advisable to adopt that system which gave a greater degree of safety. When the neutral was earthed one relied on a single set of insulation, but where the neutral was insulated there were two such sets of insulation in series, both of which must fail before troublesome or dangerous conditions arose, and by means of the leakage indicator required by the Home Office Regulations it was possible to see that both these sets of insulation were being kept in good condition. Replying to Mr. Sayer's challenge to Fig. 1, by referring to the discussion on a Paper presented to the American Institute of Electrical Engineers by Mr. F. O. Blackwell, it would be seen that Mr. P. N. Nunn, engineer of the Telluride Power Co., stated that the conditions shown in this diagram not only could occur, but frequently had occurred on his system, which was connected as shown in the diagram. The reason the lightning arresters were the first signs of anything wrong was because these arresters were set for the normal working condition of a maximum voltage of 58 per cent. of the line volts between any point and earth, and owing to the abnormal conditions which had arisen there was, as a matter of fact, the full line volts between two phases and earth. As to the advantage of the earthed neutral enabling the designer to know the exact voltage with which he had to deal, this, of course, was so, but with the average colliery voltage, say, either 650 or 3,000, the difference to the designer was quite negligible. Mr. Patchell was correct in his remarks about President Scott, but judging from the Paper read by Mr. Marchant before this Institution a short time ago the conditions in America were still very much the same, and although it would appear that earthing the neutral on these extra high-tension lines would be the best thing to do, the majority of American plants worked very satisfactorily with a delta connection and insulated neutral. With regard to Mr. Wordingham's suggestion that there should be no half measures, and the neutral be earthed with as low a resistance as possible, such a practice seemed more suitable for a supply station than for the average colliery installation, where the object was to reduce any liability to flashing or arcing underground as much as possible. The author agreed that armouring of cables was very desirable, and on high tension possibly absolutely necessary, but the fact must not be overlooked that in many collieries there were salts or acids which attacked the armouring, and Mr. Knight, of Messrs. Callender's, in speaking recently at Barnsley at a meeting of the Institution of Mining Electrical Engineers, stated that he knew collieries in Yorkshire where the armouring would not last three weeks. Of course, no reliance could be placed on armouring under these conditions. As to Mr. Wedmore's remarks, the fact that there were only 1 per cent. of electrical deaths did not convey very much until one considered that during 1908 approximately 1,280 people were killed in mines and collieries from all causes, and about 14 from electrical causes, and of these 14 some were pure accidents and some wilful carelessness. The main points which the author had endeavoured to bring out in his Paper were: (1) As long as the earthing of motor cases and switch cases was effectively maintained there was no danger from shock, but as soon as this earthing was faulty dangerous conditions could arise, against which neither leakage trips nor other devices could protect. (2) That wherever there was an earthed neutral the danger of these conditions was increased. The author's description of the size of earth wire was criticised, but it appeared unnecessary to specify that the wire should also be mechanically strong, as this was so obvious. Finally, the author saw nothing in the arguments brought forward to cause him to change his opinion that while there were no doubt certain installations where it was better to earth the neutral, it would be unwise to do this without first taking into account the particular conditions of each installation.

CORRESPONDENCE.

ON THE EFFECT OF SHUNTING INDUCTIVE COILS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have to thank Mr. G. W. O. Howe for correcting (in your issue of April 22nd) the misinterpretation of the late Mr. H. E. Harrison's experiment which occurred in the Paper by Mr. Eckersley and myself on the Insulation of Inductive Coils. Mr. Howe's simple geometrical proofs not only elucidate the



problem, but give immediately two of the approximate formulas. Permit me now to state Mr. Harrison's interesting result, putting his geometry into algebraical form for greater definiteness.

If r be a non-inductive resistance in series with a choking coil (R, L), *in some cases* the total impedance is *increased* by shunting the choker by a resistance S. This may be proved as follows:—By the usual symbolic method it is easy to show that the total impedance (Z_1) is given by the equation

$$Z_1^2 = \frac{[r(R+S)+SR]^2+(S+R)^2L^2\omega^2}{(R+S)^2+L^2\omega^2}.$$

If the values of R, L, r and ω are suitably chosen, this expres-

Digitized by Google

sion has a maximum for a value of S between ∞ and 0. For example, when R=1, r=20, and $L^2\omega^2$=10,

$$Z_1^2 = 451 + \frac{3388S - 561}{S^2 + 2S + 11}.$$

By differentiating and putting $\frac{d(Z_1^2)}{dS} = 0$ in the usual way we find that Z_1^2 has a maximum when S is about 6. Thus the total impedance without any shunt is $\sqrt{451}$; when a shunt of 6 ohms is applied, the impedance *rises* to about $\sqrt{476}$. It should be kept in mind, however, that in many cases no maximum occurs between S=0 and S=∞.—I am, &c.

Teddington, April 27. ALBERT CAMPBELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In connection with Mr. A. Still's letter in your last issue, it may be of interest to state the particular experiment to which both the late Mr. H. E. Harrison and Mr. A. Campbell were referring when discussing the peculiar effects produced by shunting inductive coils. Early in 1893 Mr. G. W. Partridge showed Mr. Harrison that shunting an inductive coil which is in series with a non-inductive resistance had sometimes the effect of increasing the impedance of the whole circuit. Mr. Campbell investigated this effect experimentally at Faraday House, and Mr. Harrison, in THE ELECTRICIAN for June 2nd, 1893, showed that the interesting and paradoxical results can be simply explained by elementary geometry.

The analytical proof is also simple. If the choking coil (0, L) be shunted by the resistance x and a resistance (r, 0) be in series with it, then if Z be the total impedance we have

$$Z^2 = \left\{\frac{x\omega^2L^2}{x^2+\omega^2L^2} + r\right\}^2 + \omega^2\left\{\frac{Lx^2}{x^2+\omega^2L^2}\right\}^2$$

and hence, by the differential calculus, Z is a maximum when

$$x = \frac{\omega^2L^2}{2r} + \frac{\omega L}{2r}(\omega^2L^2 + 4r^2)^{\frac{1}{2}}.$$

I am, &c.,

Faraday House, London, May 2. ALEXANDER RUSSELL.

THE METHOD OF DUALITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The problem discussed in the preceding letter gives an interesting example of the method of duality. By means of this method* every electrical theorem can be reciprocated into another theorem which is sometimes of greater practical importance than the first. In order to get the reciprocal theorem all we have to do is to write currents, choking coils, condensers, series, mesh, dynamo, &c., for the words voltages, condensers, choking coils, parallel, star, motor, &c., in the first theorem. Similarly to deduce the formulæ for the second theorem from the formula for the first we have merely to write C, E, 1/R, K, L, &c., for E, C, R, L, K, &c. For example, Partridge's theorem can be stated as follows:—

1. When a constant effective P.D. is applied at the terminals of the conducting path afforded by a non-inductive resistance R in series with a shunted choking coil, the effective current in the main is a minimum when

$$x = \frac{\omega^2L^2}{2R} + \frac{\omega L}{2R}(\omega^2L^2 + 4R^2)^{\frac{1}{2}},$$

where x is the non-inductive resistance shunting the choking coil L.

The reciprocal theorem is:—

2. When the effective value of the current in the main is kept constant and we have two branch circuits, one being a fixed resistance R, and the other a condenser K in series with a variable resistance x, then the effective P.D. between the terminals of the fixed resistance is a maximum, when

$$1/x = \frac{\omega^2K^2R}{2} + \frac{\omega KR}{2}\left(\omega^2K^2 + \frac{4}{R^2}\right)^{\frac{1}{2}}.$$

The formula in (2) is deduced from the formula in (1) by writing 1/x, 1/R and K for x, R and L respectively.

The chief value of the method, however, lies in its use for indicating more convenient methods of making measurements and for suggesting novel instruments and machines of value in electrotechnics.—I am, &c,

Faraday House, London, May 2. ALEXANDER RUSSELL.

* Russell, "Alternating Currents," Vol. I., Chapter XVII.

"ELECTRIC CABLES: THEIR CONSTRUCTION AND USE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I make a protest against the tendency of unfair and often ignorant "reviews" of technical works which appear in your columns.

With a large number of your readers, I look to such reviews for guidance before purchasing any work on a technical subject in which I am interested.

On more than one occasion recently I have happened to read reviews on books in my possession, or at my disposal, and have found points criticised ignorantly, and I must say spitefully.

The latest instance occurred in your review of Coyle and Howe's "Electric Cables, their Construction and Cost."

The first paragraph makes a peculiar reference to the Engineering Standards Committee and its "experience." The coefficient for copper as adopted by the Committee is *known* to be wrong, and has been discarded by most up-to-date cable manufacturers, and the table as published by Coyle and Howe is now generally adopted.

I should be glad if your reviewer can point out a single case where specific gravity is used erroneously, and advise him to "read" the authors' remarks on the specific gravity of paper cables. I fail to find any confusion in the chapter on telephone cables, and on this subject your reviewer is evidently an "amateur."

By some people, like your reviewer, it appears that the book was *not* wanted, as it gives too much valuable information away, which hitherto has been kept under lock and key; but for a large number of engineers the book has filled a long felt want. Although catalogues of to-day are very profuse with information, one can hardly expect in this age of "associations," trusts, &c., cable manufacturers to show their customers that after allowing a fair margin of profit a cable should cost £200, and he finds he has to pay £400 for it as the book demonstrates, I cannot imagine any *business* engineer sitting down in "satisfactory contentment."

It is very obvious your reviewer is interested in "fancy" prices being paid and keeping the customer in ignorance.

The book in question was most favourably reviewed by your contemporaries the "Electrical Review," the "Electrical Engineer," "Gummi Markt," of Hamburg and "Le Caoutchouc et Gutta Percha," of Paris.

This or any book ever published is not perfect, and I feel sure no one would appreciate fair criticism more than an author, and the least a subscriber can reasonably expect is that reviews should be free from petty jealousy, "Association" influence and wilful misrepresentation.

Finally, it would perhaps surprise your reviewer if he could ascertain how many cable works in England and on the Continent have a "*number*" of these much despised "amateur" works in daily use.—I am, &c.,

April 26. A LOVER OF FAIR PLAY.

["A Lover of Fair Play" stigmatises our reviews as being often unfair, ignorant and spiteful. A mere assertion of this character is easily made, but goes for very little. If he is right, we must conclude that "A Lover of Fair Play" knows more about the subjects at issue than do the numerous well-qualified reviewers to whom these books are submitted. This, we suggest, is improbable. In fact, their names are a sufficient guarantee to the contrary. If the criterion of a good review is that it must be favourable, nothing is easier; but THE ELECTRICIAN readers have a right to expect something more than mere colourless statements of approval. With regard to the

Digitized by Google

particular review of "Electric Cables: Their Construction and Use," we have communicated with the reviewer, who is an engineer perfectly well known in the cable industry. He sees no reason to modify his review, and he did not refer to the authors as "amateurs." "A Lover of Fair Play" would have been better entitled to notice if he had permitted us to publish either his name or his initials.—ED. *E.*]

PROF. FLEMING'S LECTURES IN TELEGRAPHY AND TELEPHONY.

At the conclusion of his recent Postgraduate Lectures given at University College, London, on the Propagation of Electric Currents in Telegraph and Telephone Cables, Prof. J. A. Fleming set an examination paper to be worked by the members of the class. As the lectures were attended by over 70 telegraph, cable and telephone engineers, and as Dr. Fleming's engagements did not permit of the individual examination of the papers, he has requested Mr. G. B. Dyke to work out the solutions, and these have now been placed in our hands. As the subject is of very general interest at the present time we reproduce the questions and answers below.

Question I.—Plot, as lines radiating from any origin, the vectors: $\cosh(0{\cdot}5+j0{\cdot}8)$, $\sinh(0{\cdot}5+j0{\cdot}8)$, $\sqrt{\coth}(0{\cdot}5+j0{\cdot}8)$.

Solution.—Writing out these functions as vectors, we have

$$\sinh(0{\cdot}5+j0{\cdot}8) = 0{\cdot}363+j0{\cdot}809 = 0{\cdot}887\angle 65°\,50'$$
$$\cosh(0{\cdot}5+j0{\cdot}8) = 0{\cdot}786+j0{\cdot}374 = 0{\cdot}870\angle 25°\,27'$$
$$\therefore \quad \coth(0{\cdot}5+j0{\cdot}8) = 0{\cdot}981\angle 40°\,23'$$
$$\therefore \quad \sqrt{\coth}(0{\cdot}5+j0{\cdot}8) = 0{\cdot}990\angle 20°\,11{\cdot}5' = 0{\cdot}929-j0{\cdot}342.$$

These vectors may be plotted as shown in Fig. 1.

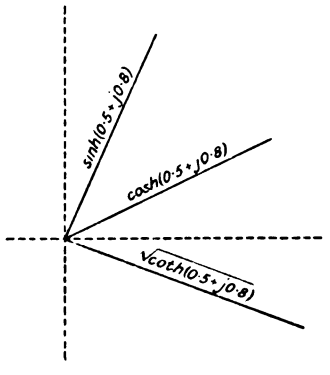


FIG. 1.

Question II.—If a length of 40 miles of standard cable (88 ohms, 0·001 henry and 0·054 mfd. per loop mile) has an alternating E.M.F. of 5 volts, and frequency $5{,}000/2\pi$ applied to one end; calculate the P.D. at the receiving end when this end is insulated, and the current if short-circuited.

Solution.—We have

$$\text{Initial sending end impedance } Z_0 = \frac{\sqrt{R+jpL}}{\sqrt{jpC}} = 573\angle 43°\,23' \text{ vector ohms.}$$

$$\text{Now, attenuation constant} = \alpha = \sqrt{\frac{Cp}{2}\left\{\sqrt{R^2+p^2L^2}-pL\right\}} = 0{\cdot}106.$$

$$\text{and wave-length constant} = \beta = \sqrt{\frac{Cp}{2}\left\{\sqrt{R^2+p^2L^2}+pL\right\}} = 0{\cdot}112.$$

$$\text{Hence attenuation length} = Pl = (\alpha+j\beta)\,l = (0{\cdot}106+j0{\cdot}112)\,40 = 4{\cdot}24+j4{\cdot}48.$$

For far end open,

$$\text{Receiving end P.D.} = V_2 = V_1 \operatorname{sech} Pl = \frac{5}{34{\cdot}70\angle 245°\,42'} = 0{\cdot}144\angle 114°\,18' \text{ vector volts.}$$

For far end short-circuited,

$$\text{Received current} = I_2 = \frac{V_1}{Z_0}\operatorname{cosech} Pl = \frac{0{\cdot}144\angle 114°\,18'}{573\angle 43°\,23'} = 0{\cdot}252\angle 157°\,41' \text{ vector milliamperes.}$$

Question III.—Taking the above cable, let a telephone receiver be placed at the receiving end, having an impedance of $1{,}275\angle 63°\,48'$ vector ohms. Calculate the current through the telephone for the same sending voltage and frequency as in Question II.

Solution.—For a line as long as 40 miles we may use the approximate formula

$$\text{Received current } I_2 = \frac{V_1 \operatorname{sech} Pl}{(Z_0+Z_r)}.$$

Now $Z_0 = 573\angle 43°\,23'$

and $Z_r = 1{,}275\angle 63°\,48'$

and $Z_0+Z_r = 1{,}233\angle 37°\,25'$

$$\therefore \quad I_2 = \frac{0{\cdot}144\angle 114°\,18'}{1{,}233\angle 37°\,25'} = 0{\cdot}117\angle 76°\,53' \text{ vector-milliamperes.}$$

Question IV.—Taking 40 miles of the above cable, let it be loaded at 2-mile intervals with Pupin coils each of effective resistance 10 ohms and inductance 0·2 henry. Calculate the attenuation constants for the unloaded and loaded 40-mile lengths.

Solution.—As the leakance is zero we have

$$\text{Attenuation constant} = \alpha = \sqrt{\frac{Cp}{2}\left\{\sqrt{R^2+p^2L^2}-pL\right\}},$$

and for the unloaded cable

$$R = 88 \text{ ohms}, \quad L = 0{\cdot}001 \text{ henry}.$$
$$C = \frac{0{\cdot}054}{10^6} \text{ farad per mile and } p = 5{,}000.$$

Hence $\alpha = 0{\cdot}106$.

For the loaded cable

$$R = 88+5 = 93 \text{ ohms}, \quad L = 0{\cdot}001+0{\cdot}1 = 0{\cdot}101 \text{ henry}.$$
$$C = \frac{0{\cdot}054}{10^6} \text{ farad per mile and } p = 5{,}000.$$

Hence the "smooth" attenuation constant $= \alpha' = 0{\cdot}032$.

$$\text{The wave length constant} = \beta' = \sqrt{\frac{Cp}{2}\left\{\sqrt{R^2+p^2L^2}+pL\right\}} = 0{\cdot}370.$$

$$\text{Hence the wave length} = \frac{2\pi}{\beta'} = 17 \text{ miles.}$$

We have therefore 8½ coils per wave, and hence the "smooth" attenuation constant 0·032 gives a very close approximation to the true value.

Question V.—Given a submarine cable 1,000 miles long, having resistance 3 ohms and capacity ¼ mfd. per nautical mile, worked without terminal condensers. Assume a letter S sent, uncurbed, with 20 volts

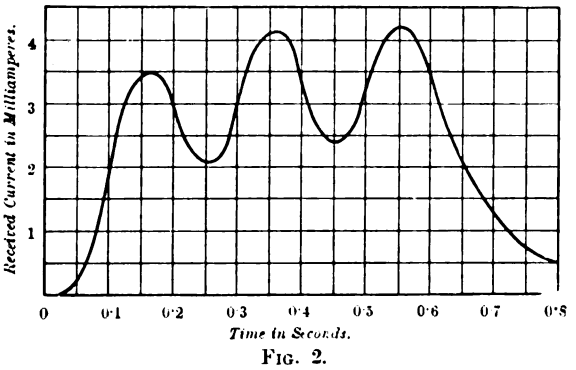

FIG. 2.

impressed E.M.F., each dot and each space being 0·1 second long. Predetermine the curve which would be drawn by the pen of the syphon recorder at the receiving end.

Solution.—

$$\text{Let } \mu = \frac{\pi^2}{CRl^2} = \frac{\pi^2}{\frac{1}{3\times 10^6}\times 3\times 10^6} = 9{\cdot}87$$

and let $e^{-\mu t} = \theta$

and $f(\mu t) = \frac{1}{2}-\theta+\theta^4-\theta^9+\theta^{16}-$, &c.

Then if the letter S is sent, the received current I_t after a time t is given by

$$I_t = \frac{2V}{Rl}F(\mu t) = \frac{1}{75}F(\mu t) \quad \text{in this case.}$$

$$\therefore \quad I_t = \frac{1}{75}\{f(\mu t)-f(\mu, t-0{\cdot}1)+f(\mu, t-0{\cdot}2)-f(\mu, t-0{\cdot}3)+f(\mu, t-0{\cdot}4)-f(\mu, t-0{\cdot}5)\}.$$

The received current can, therefore, be calculated for any assigned value of t. If this is done for several values, and the results plotted, the form of the received signal may be drawn as shown in Fig. 2.

Question VI.—If a power transmission line 50 miles long consists of a pair of No. 4 S.W.G. copper wires each 5·9 mm. diameter placed 1 metre apart, and if these lines are carried on poles 40 ft. above the ground,

Digitized by Google

calculate the capacity, inductance and impedance of this line for currents of a frequency of 25 ∞, assuming the copper resistance to be 2 ohms per loop mile.

Solution.—Capacity per mile in microfarads.

$$= \frac{0{\cdot}0194}{\log_{10}\frac{2D}{d}},$$

where D=distance apart in centimetres. d=diameter of wire in centimetres.

$$= 0{\cdot}00766 \text{ mfd.}$$

$\therefore$ Total capacity = 0·383 mfd.

Inductance per mile in microhenrys

$$= 1{,}483 \log_{10}\frac{2D}{d},$$

$$= 3{,}752 \text{ microhenrys}$$

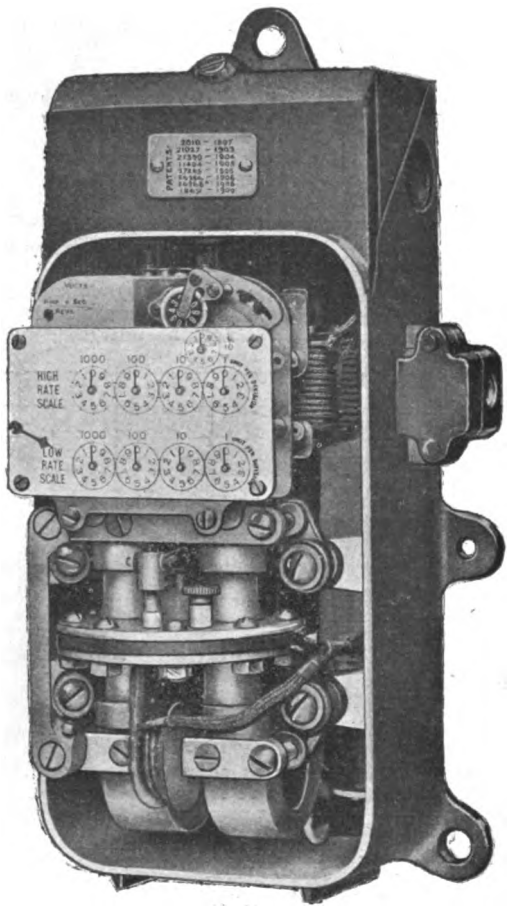
$\therefore$ Total inductance = 0·1876 henry.

Initial sending end impedance $= Z_0 = \frac{\sqrt{R+jpL}}{\sqrt{jpC}}$

$$= 1{,}318 \angle 36°43' \text{ vector ohms.}$$

FERRANTI TWO-RATE CONTINUOUS CURRENT METERS.

Messrs. Ferranti have added to their activities in the meter world by the production of a two-rate continuous-current meter, an inside view of which is shown in the accompanying illustration. This



Inside View of Ferranti Two rate Meter.

type of meter is provided with two sets of dials, each of which indicates the energy consumption in Board of Trade units. The lower dial indicates the consumption during one portion of the day and is generally arranged to indicate that portion of the energy consumed at the cheaper rate. The higher dial indicates the consumption of that portion of the energy charged at the higher rate. In general arrangements the meter is of the Ferranti-Hamilton standard continuous-current type, while the two-rate train consists of two sets of recording dials of the ordinary kind and an intermediate change-over gear of novel construction. The meter spindle drives the $\frac{1}{100}$ and $\frac{1}{10}$ unit spindles in the usual manner. This arrangement is an advantage which is not usually possessed by two-rate meters, as it allows testing to be effected much more easily. The $\frac{1}{10}$ unit spindle drives the first wheel of the intermediate change-over gear wheels, and this in its turn drives two others of a wheel train, the latter of which may gear either with the wheel on the unit spindle of the lower recording dials or with the wheel on the unit spindle on the higher recording dials, according as the change-over lever is in the low or high-rate position. The construction of this gearing is epicyclic in character so that by the rotation of the lever about the centre of the first wheel no rotation of the second wheel occurs when these two wheels are of the same diameter. In the act of changing from registering on one dial to registering on the other dial no rotary motion is given to the dials. A shunt circuit, consisting of an electromagnet, resistance and automatic time switch all in series and taking about $\frac{1}{60}$ of an ampere, provides the energy to operate the change over from low rate to high rate. The automatic time switch "makes" the shunt circuit at the beginning of the high-rate period. This energises the electromagnet which attracts the armature and operates the change-over of the gears. The shunt circuit is "made" during the whole of the high-rate period and the meter registration is on the higher dials for this period. At the end of the high-rate period the automatic time switch "breaks" the shunt circuit and allows the armature to fall away and bring the dial wheel out of gear with the high-rate wheel and into gear with the low-rate wheel. The shunt circuit is "broken" during the whole of the low-rate period and the meter registration is on the lower dials for this period.

LEGAL INTELLIGENCE.

The Electrical Co. v. Thomas, Son & Co.

The hearing of this case, which has lasted 40 days and has established a record as a reference before the Official Referee, was concluded last week, when Mr. Pollock heard further evidence by plaintiffs in connection with the defendants' counterclaim.

Mr. Chas. P. Sparkes, said he had visited the Lynvi Colliery in 1908 at plaintiffs' request and examined the plant there. This plant was suitable for the work, but he advised plaintiff company that there were not sufficient reserves. There was no spare generator and the pumps were not arranged to the best advantage. The sump was very much smaller than usual, and the danger was of loosing the machinery by being drowned out. In his opinion the failure of the machine to excite was probably due to the brushes being allowed to get loose or the motor to get dirty. He did not know of any other reason. It was very necessary to have a skilled man to work the plant. In the early days, when it was very difficult to get a skilled man, trouble with the commutator was far more important than it was at present. He knew the plant which plaintiffs had supplied, and having regard to the enormous risks they ran witness reported to them that to run a single generator for over 2,000 hours involved great risk to the contractors, greater than any ordinary contractor would take. He advised plaintiffs to come to a settlement with defendants. In his opinion it was not business for the plaintiffs to go on running so great a risk as keeping the "slant" unwatered with such a plant. There was undoubtedly some mistake in connecting the exciter that might cause some of the trouble complained of in regard to the machine. If either of the current "paths" were broken—that was to say, if the generator "path" was broken through a "fault," the machine could not produce any current On the other hand, if the field were improperly connected the machine would be unable to build up sufficient field to give any current. Anyone, however, putting the machine to work originally would detect this very easily. If anything went wrong with an exciter the usual method of endeavouring to ascertain the trouble was first of all to increase the speed of the machine. It was quite possible that a machine, owing to shock in transit, or being knocked about in some way, might entirely lose its residual magnetism, and then when it was put up in the first instance it would be necessary to use a small battery to excite it. Once, however, it had become magnetised, unless the machine stood for a very long period, was subjected to vibration, or was knocked about, it was not very likely that it would lose its magnetism. It was quite possible for a machine to lose its residual magnetism if taken to pieces. After such an operation the residual magnetism of a machine certainly got weaker, and he thought that in this instance the question of speed of the engine had been overlooked in the endeavour to get the exciter to work after it had been cleaned.

This concluded plaintiffs' evidence on the counterclaim.

Counsel having addressed him, the Official Referee delivered judgment on Saturday. He reviewed the evidence, &c., at considerable length. Considering, he said, how Mr. Thomas had always urged upon the Electrical Co. the necessity of proceeding with their work without delay, it was a matter of surprise that he took a month to conclude the contract. It was also curious that Dec. 23 was put forward as the date the plant should be erected. On Dec. 21, however, defendants wrote to plaintiffs to say that the buildings at the mine were not ready to receive the plant, and that Mr. Thomas would write to the plaintiffs when they were ready to receive it. Therefore, the delay up to that time was obviously due to defendants and not to plaintiffs. There were entries in the daily reports of defendants showing that considerably

Digitized by Google

later than that the building was not in a finished state. As regarded the difficulty of the belt, and the point which was raised that it was not included in the contract, he was of opinion that, even assuming the belt was shown on the drawings, that would not help Mr. Thomas's case. This also gave rise to more delay, for which plaintiffs were not responsible. As was usual during this time, defendants were complaining of delay, and plaintiff company were writing making excuses, because they did not want to offend defendants, but it seemed to him that plaintiffs had good ground for saying that the delay was not theirs. He found that the contract of 1905 was completed somewhere about the middle of February, 1907, and it was clear upon the evidence that between August, 1906, and June, 1907, some 1,594 tons of coal were got out of the mine. There was no doubt that difficulties occurred during that time. There were difficulties with the exciter, which failed from time to time, but that failure did not interfere with keeping the water out of the mine or with working the coal. In his view, the chief difficulty, if not the whole difficulty, in regard to the exciter was due to the improper attention bestowed upon the machine by those in the employ of defendants. There was obviously no one there who knew anything at all about the electrical plant. There was no expert of any kind there on defendants' behalf, and when an expert went down on plaintiffs' behalf the machine was put in order and worked very well. There was a suggestion that the trouble with the exciter was due to some fault for which plaintiff company were responsible, but witnesses called for plaintiffs showed that the machine ran perfectly well for a certain length of time and the difficulty could not be due to any inherent defect in the exciter; but, on the other hand, was due to improper attention. He therefore came to the conclusion that there was no material defect in the machine. It was pretty obvious that the steam pipes were responsible for some of the mischief which arose. Mr. H. W. Thomas went so far as to say that he cleaned the exciter 12 times in one day, but he (Mr. Pollock) did not for a moment believe that. As to the flooding of the mine he did not believe that the accident arose from anything for which plaintiff company were responsible, and there was no proper evidence upon which he could base such a finding. The new agreement after the flooding out of the mine was entered into, and defendants' contention was that this new agreement was a continuation of the agreement made in 1905, and upon this point of view Mr. Thomas had based the counterclaim. He (Mr. Pollock) did not agree with that contention, and, in his opinion, the agreement of June, 1907, was an entirely fresh one. At that time, plaintiffs had completed their contract, but the mine was flooded, and it was necessary to take some steps to unwater it. They came to the very simple conclusion that they must start afresh to deal with this uncontemplated state of things, and they showed that they intended to hang up the proceedings and leave the dispates which had arisen over the 1905 contract to be settled afterwards. The new agreement was consequently entered into, and at this time plaintiff company were undoubtedly desirous to show that the plant was effective for unwatering the mine, because they did not wish it to be said by anyone that their plant could not do the work. This new contract for unwatering the mine, however, had nothing whatever to do with the original contract under which they had only got to supply pumps that would be capable of dealing with the work. The new contract was to get rid of the water in the mine whatever the amount of it was. In entering into this contract plaintiffs were going to great expense and were doing so for the benefit of defendants. They declared that they would get rid of the water and they ultimately did so, but they did not say they would do so within any specified time. As soon as they started to deal with the matter Messrs. Thomas began to complain, but Mr. Thomas was in the habit of complaining, and that could not be avoided. The Official Referee quoted freely from the correspondence between the parties, but he came to the conclusion that the damages defendants claimed were too remote, and he did not agree that defendants had suffered the enormous amount of damage they claimed nor could such damages be recovered. The strike was the actual cause of the mine being flooded and not any failure on the part of plaintiffs. In fact, he thought plaintiffs had acted very reasonably throughout. The evidence given on behalf of defendants was unreliable. The time the case had occupied (40 days) was wholly unjustifiable, and had arisen in a great measure from the way in which defendants had brought it forward. They had put forward a counterclaim for £31,000. Most of the time had been occupied in dealing with the counterclaim, and many of the items in that claim had been grossly exaggerated. Documents to which plaintiffs ought to have had access were not produced until the inquiry had been in progress some time; no survey books were produced, and there was the greatest difficulty in getting hold of the plans. He had taken a general view of the material facts of the case, and upon those material facts he had come to the conclusion that plaintiffs' view was right and that the plaintiffs had, subject to a small matter which he would deal with, completed their contract in February, 1907, sufficient to entitle them to recover those items which he should mention; and that with regard to that part of the case—that was the only part of the case with regard to which Mr. Oliver Thomas could recover any damage at all—all the subsequent operations in the mine were conducted under the agreements of June 20, 1907, and Nov. 15, 1907—and that no damages were recoverable (they were not claimed indeed) on behalf of Mr. Oliver Thomas in respect of those two matters. He had not been put in a position on behalf of defendant to enable him to say what damage he was entitled to in respect of that portion of the period during which it was admitted there was a breach by plaintiffs of their contract. There was not a fraction of evidence on behalf of defendants to which he could appeal to enable him to deal with it. It was quite clear to his mind, having regard to the fact that the mine was kept unwatered from Aug. 11, 1906, that the damage must be very small. He thought it could be only in respect of any extra coal used, any possible extra labour (he did not know whether there was any caused) and any extra wear and tear of the steam pumps employed while plaintiffs failed to complete their contract. For plaintiffs it was admitted it might amount possibly to £50. He accepted that admission, and he found £50 for that. Upon that basis he found in favour of plaintiffs on the claim. The items were £1,150, £51. 1s. 4d., £87. 18s. 4d., £4. 17s., £10. 4s. 7d., £2. 4s. 6d., making a total of £1,306. 5s. 9d. There was the set-off of £151. 4s. 10d., and also the £50 damages. Deducting those items from the £1,306. 5s. 9d. made the amount £1,105, for which there would be judgment, with costs of claim and counterclaim.

Reid Newfoundland Co. v. Anglo-American Telegraph Co.

On Thursday last week the Judicial Committee of the Privy Council (Lords Macnaghten, Collins and Shaw of Dunfermline, and Sir Arthur Wilson) heard legal arguments in an appeal from a judgment of the Supreme Court of Newfoundland.

Mr. Danckwerts, K.C., and Mr. R. E. Moore were counsel for appellants; Sir Robert Finlay, K.C., and Mr. Rowlatt for respondents. Respondents are successors of the New York, Newfoundland & London Telegraph Co., incorporated under an act of the Newfoundland Legislature in 1854. By sec. 14 of that statute the use of any part of the territory of Newfoundland by any other persons than the company for telegraphic communication was prohibited for 50 years, subject to a right of pre-emption by the Government of the colony. Appellants were lessees of the Newfoundland railway system. In 1907 they erected along a section of their railway a line of telegraph, which it was proposed to use for working their system, and it was in respect of this intention that the present action was brought by respondents, on the ground that such action was an infringement of an agreement made in 1888 between them and the Newfoundland Railway Co. The question in dispute was whether under that agreement respondents had the right to prevent appellants from erecting and using such a line of telegraphs. The Supreme Court decided in favour of respondents, and ordered appellants to remove the telegraph line in question.

Their lordships reserved judgment.

Valuation of Tramways.

In the Bill Chamber of the Court of Session (Edinburgh) on Thursday last week Lord Dundas delivered his considered judgment in the appeal by Glasgow Corporation against the valuation of the municipal tramways made by the Assessor of Railways and Canals. The yearly rent or value of the undertaking had been fixed by the assessor at £278,070, but for the Corporation it was urged that the figure should be £230,573. Lord Dundas has found the value of appellants' undertaking to be £258,838, and to that extent he allowed the appeal. In delivering judgment, Lord Dundas said that the principal, if not the only, question involved was whether or not the word "railway" as it occurred in sec. 3 of the Valuation of Lands (Scotland) Amendment Act, 1867, was sufficiently wide to include "tramway," so as to make appellants' undertaking a subject of compulsory assessment by the Assessor of Railways and Canals. The argument for appellants was forcible, but he allowed the argument of assessor's counsel to proceed, because (1) the point seemed to be fairly raised by the alternative (in one view the primary) contention of appellants, and (2) his lordship desired to have the assistance of counsel upon a point which, as his lordship thought, it was pars judicis to determine apart from the attitude assumed by counsel upon either side. Leaving authority out of account, he would come without much doubt or difficulty to an affirmative conclusion upon the question he had indicated. There could be no doubt that a tramway was a kind of railway. Each ran upon rails with flanged wheels. He had not, he confessed, been able to see any force in the suggested differences between a railway proper and a tramway. Their structural character was substantially the same. The definitions of "tramway" in dictionaries and in the common use of language brought it within the idea and meaning of a railway. He therefore held, in the absence of authority, that the language of sec. 3 of the Act of 1867 was sufficiently wide to include, for the purpose in question, appellants' undertaking, and he thought that sec. 7 of the Valuation of Lands (Scotland) Acts Amendment Act, 1894, pointed in that direction. The collocation of the words there used seemed to him important and significant. The section spoke of "railways, tramways, canals," &c., and the word "tramways" appeared to be used as exegetical of railways, and was placed between them and the other compulsory subject of valuation by the assessor, namely, "canals." It looked as if the draughtsman in 1894 assumed that tramways were, in the eye of the law, a form of railway, and as such within the compulsory purview of the Assessor of Railways and Canals. But when he turned to authority he found a direct and satisfactory confirmation of his own a priori opinion. In 1873 Lord Shand, sitting as Lord Ordinary on the bills, decided a case on appeal by Glasgow Tramway & Omnibus Co. against the valuation of their undertaking by the Assessor of Railways and Canals. That decision proceeded upon the preliminary point with which he (Lord Dundas) was not concerned. But Lord Shand said:—"A tramway is a species of railway, and railway and tramway undertakings respectively take their names as such from the fact that they possess and use for purposes of conveyance rails fixed in the ground, but differing somewhat in form of construction. In the sense of the Valuation Acts the Lord Ordinary is of opinion that a tramway company is included under the term railway company, which term is not limited to such railway companies as use locomotive power." His lordship could not doubt that in

Digitized by Google

expressing that opinion Lord Shand had before him the language of sec. 3 of the Act of 1867, and it appeared that his lordship's opinion had been adopted and followed in practice ever since. In these circumstances the Lord Ordinary was prepared to decide that appellants' undertaking fell properly within the jurisdiction of the Assessor of Railways and Canals. Certain English cases referred to by counsel did not appear to have any direct bearing upon the question at issue, involving as it did the construction of a particular section in an Act of Parliament applicable to Scotland. That point being determined, there was little or nothing more that required to be decided. Counsel agreed that if he should come to the conclusion he had reached the valuation should stand for this year at £258,838, and he would find and declare accordingly. He might observe, however, that while the mode in which the assessor had been in use to ascertain the amount of the deduction authorised by the statute seemed quite a reasonable one, it was not in strict conformity with that prescribed by sec. 3 of the Act of 1867.

Wright v. Peters.

Last week Mr. Justice Jelf and a common jury heard this action in which plaintiff (an electrical engineer) sought to recover from defendant, a solicitor, the balance of £97 for work done at his house.

Mr. DRURY, for plaintiff, said that in April last plaintiff got into communication with Addinell & Co. (Ltd.), electrical engineers, of Snow-hill, London, E.C., and he was asked by them to give an estimate for work to be done at defendant's house and for a time he thought he was dealing with the company. He agreed to do the work for £97. The time came when he wanted to be paid some money on account, and on April 22 he got a letter signed S. G. Addinell, one of the directors, enclosing a cheque for £25 and stating that as they could not get the signatures of the other directors they sent their solicitor's cheque. That cheque was signed "McIntire and J. Capel Peters." Defendant thought that extraordinary but continued to do the work. However, he could get no more money, and subsequently discovered that on May 18 a receiver had been appointed on behalf of the debenture holders of the company, which seemed to have come to grief. Plaintiff went to Somerset House where he found that the company had a nominal capital of £1,500 in £1 shares and that 1,000 of them had gone to the promoter. The solicitors to the company were stated to be Messrs. McIntire & Peters, and the latter appeared to be a director and secretary as well. The only other directors were Messrs. Addinell and McIntire. Messrs. Peters and McIntire seemed to have taken charges upon the whole of the company's property and when the receiver went in there was only 9d. in cash belonging to the company.

His LORDSHIP said that plaintiff clearly had no ground of action against defendant, as the transaction had been with the limited company. It was not a case for the jury, and judgment must be for the defendant, with costs. An application for stay of execution was refused.

British Aluminium Co. (Ltd.)—On Tuesday Mr. Justice Swinfen-Eady dismissed, by consent, two petitions for the winding up of this company.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Applications are invited for the position of borough electrical engineer at Keighley. Candidates must be thoroughly trained engineers, with a knowledge of both h.t., three-phase alternating and d.c. supply. Applications to the town clerk, Mr. Wm. Bagshaw, Town Hall, Keighley, by May 18. See also an advertisement.

An engineer is required at a private house, to drive suction gas plant for electric lighting, and have care of accumulators, telephones, &c. Applications to Secretary, Avenue House, Church End, Finchley, N. See advertisement.

A draughtsman is wanted with first-class experience in d.-c. motor design. See an advertisement.

There is a vacancy for a premium pupil at Watford electricity works. Applications to the Chief Engineer. See an advertisement.

The Electricity committee of Salford Corporation invite applications from thoroughly experienced men, with first-class technical training, for the position of superintendent of the hired meter and testing department. Commencing salary £120, rising to £180. Particulars from the borough electrical engineer, Mr. Victor A. H. McCowen, Electricity Works, Frederick-road, Pendleton, Salford. Applications to the town clerk, Mr. L. C. Evans, by mid-day Monday, May 9.

The Belfast Commissioners under the Irish Universities Act, 1908, will proceed at an early date to the appointment of a professor of engineering. Particulars from the Secretary, Mr. Arthur Jaffe, Queen's University, Belfast.

A junior lecturer and demonstrator in physics is required at the University of Sheffield. Salary £150 per annum. Applications to the Registrar by June 1.

Bridlington Council have appointed Mr. Geo. Robinson electrician at the Prince's Parade.

Abertillery Council have appointed Mr. Dan Lloyd manager of their electricity works, and Mr. E. O. Rake electrician.

Mr. C. W. Salt, chief assistant electrical engineer at Bradford, has been appointed borough electrical engineer at Torquay, out of about 150 applicants. Mr. Salt has been five years at Bradford, prior to which time he was second assistant electrical engineer at Croydon.

The following were selected to appear before the Electric Light committee:—Messrs. A. W. Clegg (Accrington), J. M. Keenan (Torquay), J. W. Turner (Huddersfield), B. S. Hornby (Bolton), C. N. Hefford (Leeds), and C. W. Salt (Bradford). The committee recommended Mr. Salt by seven votes to three for Mr. Keenan. It was proposed, as an amendment to the approval of the recommendation, that Mr. Keenan be elected. On a vote Mr. Salt received 18 votes to Mr. Keenan's 12, three members not voting. Mr. Salt was accordingly declared elected.

St. Pancras (London) Electricity commitee has promoted Mr. G. T. Rawson, second clerk, to the position of first clerk at a salary of £150, increasing annually by £10 to £200.

Mr. C. E. Smith, chief engineer of the Rosario Electric Co., has been appointed chief engineer of the Compañia de Electricidad de la Provincia de Buenos Aires.

Mr. W. B. Adams has been appointed engineer-in-charge of the generating station of the Rio Tinto Copper Co., Spain.

EDUCATIONAL NOTICES.

Technological Scholarships.—The West Riding (of Yorkshire) County Council offer minor technological scholarships (value up to £50 each per annum) tenable by persons who have had practical experience at a trade for at least one year and have concurrently attended day or evening classes, or are pupils about to leave secondary schools. Full particulars from the Education Department (Technical Branch), County Hall, Wakefield.

Faraday House.—Major O'Meara, late R.E., C.M.G., will deliver a special lecture to the Third Year Students on May 20, commencing at 10 a.m. The subject of the lecture will be "Depreciation."

Belfast Municipal Technical Institute.—The new extension of the buildings of this institute, rendered necessary by the demand for increased accommodation, was formally opened by the Lord Mayor (Coun. R. J. M'Mordie) on Tuesday.

Accrington.—The Council offer to supply electricity in bulk, on certain terms, to Haslingden, for seven years.

Acton.—Mains are to be laid at a cost of £150 to supply current to 14 new houses.

At the last meeting of the Electricity committee the question of reducing the expenditure of the electricity department was considered.

Coun. YOUNG asked the chairman questions as to the duties of the electrical engineer (Mr. J. M. Blair) and his assistant, and later sprang a motion that the services of Mr. Blair should be dispensed with.

Coun. WITHERS thought if it was the intention of the committee to pass such a motion it should not go forward on the same minutes as the vote of censure.

Coun. CRANE said he could not vote for such a serious motion as discharging one of the chief officials without further considering the matter. When he came to the meeting he had no idea that such a motion was to be proposed, and he should not like to feel that they were doing anything that would damage the prospects of one of the officials by passing a surprise motion.

Coun. YOUNG said he had no wish to do harm to Mr. Blair, but acted on the ground of economy, as they could not afford to keep him.

Mr. BLAIR pointed out to the committee that the working of the undertaking had been a very up-hill one from the start, and now that they were turning the tide and beginning to show a profit he scarcely thought it fair to him to dispense with his services.

After further discussion, the resolution of Coun. Young was altered as follows:—"That the electrical engineer be requested to send in his resignation, to terminate in three months' time." The motion was carried by 5 votes to 2.

The report has, however, been referred back.

Belfast.—The plebiscite on the proposal of the Corporation to purchase the Cavehill and Whitewell tramways has resulted as follows: For the purchase, 26,485 votes; against, 7,925; majority for purchase, 18,560.

Blackpool.—The borough electrical engineer and tramways manager (Mr. C. Furness) reports that during the year ended March 31 the total units generated were 3,884,151, a net increase of 68,759. 8,692 tons of coal (8,316 last year) were used, costing £4,450 (£4,660).

There was an increase of 128 in the number of consumers, compared with 91 increase in 1908-9, and it is anticipated that when the official figures are obtainable the result of the past year's working will show a surplus of approximately £6,500 after meeting all expenses and providing for interest and sinking fund charges. The estimated surplus was £6,000. In 1907 the surplus was £8,229; in 1908 £8,456; and in 1909 £7,255.

Bournemouth.—On Tuesday the Corporation received a report from the tramways manager (Mr. C. W. Hill) recommending that

Digitized by Google

the conduit system through the centre of the borough should be abandoned, and overhead construction substituted. Mr. Hill estimates that a saving of £3,000 per annum would thereby be effected. The report states that the conduit causes more disorganisation of the system than anything else, and the loss of revenue is considerable, apart from the great dissatisfaction to the travelling public. The report has been referred to the Tramways committee.

Brazil.—The Ministry of Communications and Public Works is to expend £52,000 on the construction of a telegraph line between the States of Matto Grosso and Amazonas.

Brighton.—The wiring at the Pavilion is to be overhauled at a cost of £500.

Burton-upon-Trent.—The past year's working of the electricity department shows a surplus of £1,473, compared with £881 in 1908-9.

£1,346 is being transferred to renewals fund. Sales of current for lighting decreased by £206, owing to extended use of metal filament lamps and to bad trade, but supplies for power and heating have increased by £25 and for tramways £38. Fuel cost has decreased by £641 (0·284d. per unit compared with 0·386d.), and the engineer (Mr. P. J. Pringle) calls attention to the fact that the fuel now used is little more than smudge. Gross profit is £6,621 (against £5,866). Lamp connections have increased 47 per cent., due to reductions in price, the use of metal filament lamps and economy exercised by consumers. Power units produced £2,163, the average price being 0·953d. per unit. Connections for power and heating are equal to 977 H.P. Works costs were 0·712d. (against 0·810d.), total costs 0·918d. (1·033d.), and capital charges 0·808d. (0·79d.). 80 per cent. of the total horse-power for power is supplied on the restricted hour principle, and the mean price paid by these consumers is 0·855d. per unit. It is calculated that the generation of current for this class is only about 35 per cent. of the revenue. Total revenue was £12,474 (against £12,444); units sold 1,529,600 (against 1,527,841), number of (equivalent) 8 c.p. lamps connected 34,829 (33,615); and maximum load for lighting and power 500 kw. (504 kw.) and for traction 375 kw. (as in previous year).

Cheltenham.—An inquiry was held last week into the Council's application for sanction to borrow £4,000 for the electricity undertaking.

The TOWN CLERK stated that the total amount of the loans already sanctioned was £180,760, and the total amount expended on the undertaking £162,632, leaving an unexpended balance of £18,078.

The Inspector (Mr. H. Ross HOOPER) asked how the balance was arrived at, but neither the town clerk (Mr. Seacome) nor the electrical engineer (Mr. Bache) was prepared to furnish the details. Mr. Bache explained that since his appointment (five years ago) he had allocated the capital expenditure strictly to the purposes for which the loans were obtained; but in the earlier days of the undertaking that practice had not been followed, and it was impossible to say exactly how much of certain loans remained unexpended, though he could give approximate figures.

The INSPECTOR expressed himself dissatisfied with that method of keeping the accounts. The loans raised ought to be ascertainable within even a few pence, else how were they to know how the concern stood at any time? He did not know how they could proceed with the present application if they could not tell him how the unexpended balance was made up. Where was the necessity for borrowing another £4,000 if they had an unexpended balance of £18,078 in hand?

The TOWN CLERK replied that the money was not in hand. What he meant by "unexpended balance" was the aggregate amount of money they had taken power to raise under different loans, but had not raised.

The INSPECTOR: Then these balances should have been cancelled.

The TOWN CLERK stated that he was taking steps to get that done.

The INSPECTOR asked to be furnished with a full statement of the capital expenditure up to March 31, 1910, with the position of each separate loan. When that was ascertained he strongly advised the Corporation to cancel the unexpended parts of the loans and to start with a clean sheet as from April 1, 1910. £1,000 of the present loan was for meters, and he reduced that to £500. £1,000 was for services, and £2,000 for mains, and the Inspector expressed himself favourable to the loans for those purposes, adding £500.

Coding Telegrams.—Some discussion has arisen round a statement made by Mr. George G. Ward, manager and vice-president of the Commercial Cable Co., as to the extent to which telegraphic messages are coded for sending over the submarine telegraph cables of the world with an almost irreducible minimum of error or necessity for repetition.

Mr. Ward, in a letter to the Speaker of the Canadian Senate on the subject of the bill for controlling cable rates which has recently passed the Canadian House of Commons, stated, as an example of the experience of the cable companies, that 147 coded words were used to represent 2,940 words of plain text.

As a reply to Mr. Ward one writer (in the "Financial News") asserts boldly that Mr. Ward exaggerated the number of plain words which such coded messages can contain, and in proof of these statements takes the A.B.C. Code, and finds that only 476 words are represented in 147 coded words. We would point out that in a discussion of this kind it is useless to adopt the public codes as representing the last word in coding skill. Codes like the A.B.C. are intended for the use of the general public chiefly, and bear no relation in the matter of condensation and completeness to the hundreds, nay thousands, of private codes in use in which the reduction in the number of code words necessary to convey lengthy messages has been reduced to a fine art. It may be taken for granted that Mr. George Ward's figure is that of actual experience. We have before us at the time of writing a private code which approximates very closely to Mr. Ward's estimate, and which, moreover, can be used in a manner to considerably increase the number of words given by Mr. Ward.

It is interesting to note that, if 147 words (representing 2,940 plain language words) can be sent over the Atlantic cables for £7. 7s. sterling, this sum represents actually $\frac{3}{5}$d. per word, and that, assuming the code words to represent only half the number of plain words given by Mr. Ward, such coded telegrams amplified into plain language words would cost only 1¼d. per word over the Atlantic cables.

Derby.—Sanction to a loan of £9,850 for additional plant, mains, services and motors has been applied for. Mains extensions at a cost of £940 have been sanctioned.

Dock Lighting.—Belfast Harbour Commissioners decided on Tuesday to purchase a 65 H.P. Allen steam dynamo, 15 arc lamps, switchboard, &c., at £1,947, for lighting the new graving dock.

Doncaster.—The tramway extension to Marshgate was opened for traffic on Wednesday.

Dundee.—On Saturday the inauguration took place of the system of electric lighting extending the whole length of the High-street and Bank-street, Lochee, the lamps numbering 16 of the duplex Excello type. Lochee is a busy town about 2½ miles from Dundee and linked up with a service of cars.

Exhibitions.—The Imperial Russian Technical Society is organising an international exhibition of electric railway plant and apparatus.

The exhibition will be held from Aug. 15 (28 old style) to Nov. 15 (28) this year, and will be divided into three sections: (1) Applications of electricity to steam railways; (2) electric traction on main lines, light railways and tramways; and (3) utilisation of waterfalls in the generation of electrical energy for power. The committee of organisation will lay a special track on the standard gauge of a total length of 2 miles.

We have received circular No. 19 relating to the international exhibition of railways and land transport (May to November, 1910) to be held at Buenos Aires in connection with the Centenary celebrations of the Argentine Republic. The circular states that works in connection with the railways and land transport exhibition will be terminated at the date fixed for its inauguration in May, and exhibitors are requested to inform the managing committee of the exhibition in due time of the arrival in Buenos Aires of the goods they are sending, giving marks, numbers and quantities, and to pay the dues for hire of ground, &c., before remitting the goods. A model of the label to be attached to exhibits sent accompanies the circular. Senhor Ignacio Orzali is acting secretary to the organising committee.

The second Municipal and Health Exhibition, which is being held at the Royal Agricultural Hall (London, N.), will be opened to-morrow, Saturday. It will contain several features of interest to municipal engineers, borough surveyors, &c.

Edinburgh.—On Tuesday the Council approved the minutes of the Lighting committee recommending the erection of cooling towers at the Corporation Electricity works.

German East Africa.—It is reported from Frankfort-on-Main that the Governor of German East Africa has granted a concession to Herr Cieseniss, of Frankfort, for the erection of electric power works at the Pangani Falls. A syndicate is being formed with a capital of 6,000,000 marks (£300,000), and at the outset the generating plant will have a capacity of 30,000 H.P., to be afterwrads enlarged to 80,000 H.P. It is proposed to use the power for the manufacture of artificial nitrates from the atmosphere.

Glasgow.—The chief engineer of the electricity department, Mr. W. W. Lackie, has issued a pamphlet setting out the terms and conditions of supply and the general rules for the prevention of fire and other risks to be observed in wiring for the supply of electrical energy.

Grangemouth.—The Council's consulting engineers, Messrs. MacIndoe & Donald, recently reported on public electric lighting, and the Council have now adopted a recommendation of the electric Lighting committee to light several streets by metallic filament lamps

Holland.—J. H. Müller, of the Hague, has obtained a concession from the Communal Authorities of Gouda for the construction and working of electric tramways between Gouda, Haastrecht, Oudewater, Montfoort and Utrecht, and between Gouda and Rotterdam.

Hospital Lighting.—At the recent meeting of the Governors of the Meath Hospital and County of Dublin Infirmary it was decided to make a public appeal for the cost of lighting the hospital by electricity.

Hungary.—Mátyásföld Landlord Association have decided to establish electricity and water works, at an estimated cost of 281,000 kronen (£11,700), which will be advanced by the president of the Association (Mr. Josef Paulheim).

Digitized by Google

Institute of Chemistry.—The following pass list of the examinations in April has been issued:

In the intermediate examination, of 11 candidates 8 passed, viz., A. Cunningham, A. A. Eldridge, J. W. Flint, B.A., A. Gemmell, B.Sc., H. Lowe, B.Sc., J. Porter, H. Shankster, T. A. Smith. Two candidates passed the final examination in mineral chemistry (J. Shelton, J. Weintroube, B.Sc.) and one in physical chemistry (F. G. Martin). Of two candidates who presented themselves in organic chemistry, one passed (W. T. Munro); and of 12 examined in the chemistry of food and drugs, eight passed: B. M. Brown, B.Sc., C. L. L. Claremont, B.Sc., R. L. Collett, B.A., S. Elliott, L. Goodban, T. S. Haines, G. F. Morrell and S. Smith.

Italy.—An electric tramway is to be constructed shortly between Spezia and Cadimare.

Keighley.—The borough electrical engineer (Mr. J. M. Smyth) has been compelled to tender his resignation on account of ill-health.

At the meeting of the Council on Tuesday the chairman of the Electricity committee (Mr. Whitehead) said that Mr. SMyth's resignation was due to medical advice.

Mr. B. S. Brigg said he wished to associate himself with the expressions of regret at the threatened breakdown of Mr. Smyth's health and his resignation. Mr. Smyth's work in the capacity of borough electrical engineer had been very arduous, as he had had practically to plan and build up the electricity department, and he had carried it out most satisfactorily.

The report of the electrical department showed that 1,071,457 units of electricity had been sold during the 12 months ended March 31, an increase of 192,700 units over the previous year.

The tramway receipts for the year ended March 31 amounted to £8,771. 19s. 9½d., an increase of £626. 16s. 1d.

Kingston-on-Thames.—The Council have informed Maldens and Coombe Council that they are prepared, subject to the approval of the Board of Trade, to enter into arrangements for supply of electricity in Coombe on conditions to be arranged.

Leeds.—The general manager of the tramways (Mr. J. B. Hamilton), has been instructed to prepare an estimate of the cost of extending the tramways to Shadwell.

Leyton.—The surveyor has been instructed to prepare estimates for lighting the remainder of Lea Bridge-road by arc lamps, and (alternatively) by clusters of electric incandescent lamps.

Light Railway.—Bacup Corporation Light Railway Order has been submitted to the Board of Trade for confirmation. Objections by May 21.

London County Council.—On Tuesday it was agreed to lend £6,880 to Fulham for electric lighting.

Electric Cars.—An adjourned recommendation to invite tenders for 250 electric cars of the bogie truck, double-deck type, was agreed to.

St. James & Pall Mall Electric Light Co.—The adjourned recommendation of the Highways committee was submitted to the effect that no objection be offered to the proposals of the St. James & Pall Mall Electric Light Co. to vary its standard pressure, and was adopted.

Reconstruction of Tramways.—The Highways committee's proposal to expend £5,500 for the reconstruction of the existing horse tramways from Tooley-street to Deptford and the construction of authorised tramways from Evelyn-street to Nelson-street, Greenwich, was adjourned.

Cars for Hilly Routes.—In connection with the decision of the Council in June last to authorise the construction of a specimen car for hilly routes, the Highways committee reported that a car had been completed and had worked satisfactorily. The truck and magnetic brake were, however, arranged to accommodate two sets of special slot brake mechanism. As the Board of Trade were satisfied with one set of this mechanism on each car will be sufficient it is proposed that the 39 cars shall only be fitted with one set. The committee recommended that tenders from selected firms be obtained for the supply of the 39 car bodies and that the British Westinghouse Co. be asked to submit an offer for the magnetic brakes required.—*Carried.*

Marylebone (London).—The Baths committee have requested their chairman to give notice of motion to rescind the resolution adopted by the Council in February last for overhauling, re-wiring and putting into proper condition the electrical installation at the baths, and the Electric Supply committee are to be permitted to carry out the work at prime cost, plus a small percentage for supervision.

The Electricity committee have authorised the general manager to let all consumers have arc lamps at a price which allows for current at £8 per kilowatt and 1d. per unit.

Middlesbrough.—The annual report of the borough electrical engineer, Mr. H. M. Taylor, submitted to the Electric Lighting committee on Wednesday, stated that there was a net profit of £1,301 on the past year's working, against £1,277 in the previous year.

National Electrical Manufacturers' Association.—The next committee meeting will be held at Balfour House, Finsbury Pavement, E.C., on the 10th May, at 2:30 p.m.

St. Helens.—The 60 c.p. lamps in the main streets are to be replaced by 100 c.p. metal filament lamps, and 45 additional posts, with two lamps attached, are to be erected where required.

On Wednesday the Council increased the salary of the borough electrical engineer (Mr. E. M. Hollingsworth) from £400 to £450 per annum, with two subsequent increments of £25 to £500.

Salford.—The Electricity committee has decided to advertise for a successor to Mr. Victor A. H. M'Cowen, borough electrical engineer, at a commencing salary of £500, rising by biennial increments of £50 to £700 per annum.

Southampton.—An inquiry was held here last week into the application of the Council for sanction to borrow £13,000 for additional generating plant and £3,000 for mains, services and meters.

The Town Clerk gave the usual statistics and said the total amount sanctioned to March 31 last was £212,619, and the total sum expended £209,414.

The borough electrical engineer (Mr. H. F. Street) gave particulars of the growth of the electricity undertaking, and of the additional generating plant which would be necessary to cope with the increased requirements of the town.

The inspector (Mr. H. Ross Hooper) said the custom of the Board of Trade now was only to sanction loans for new plant, &c., on provisionally accepted tenders, when the bodies applying had decided exactly what work should be done and what it would cost. He suggested that the Corporation should buy meters out of revenue, for it was clear that the present system was not to the benefit of the ratepayers or the undertaking. Southampton Corporation was one of the few local bodies who were now borrowing for meters.

The inquiry was adjourned for the provision of certain statistics.

Southwark (London).—Acting on the advice of the borough electrical engineer (Mr. D. M. Kinghorn) the Electric Light committee recommend that extensions of the electricity works be carried out at an estimated cost of £6,909, including a 600 kw. turbo generator (£3,300), foundations, &c. (£180), switchgear (£300), condensing plant (£1,800), cooling tower (£1,000), and £329 for contingencies.

Stepney (London).—The Electricity committee report having been approached by large firms who require a supply of electricity for lighting and power (one is at present generating its own supply) and who desire to have a combined rate for lighting and power. Such a rate is not at present in force, but, acting on the report of the borough electrical engineer and manager (Mr. W. C. P. Tapper), the committee have decided (subject to the usual sanction) to meet the request, and recommend that to power users who are willing to guarantee a minimum half-yearly bill of £200 the rate shall be £3 per annum per E.H.P. demanded, divided into 12 monthly payments (based upon the monthly demand) and ½d. per unit for electricity consumed whether for lighting or power, provided the total lighting demand in E.H.P. does not exceed 25 per cent.; also that the committee be empowered to charge fixed rates calculated on the above scale when the load factor is guaranteed.

Sweden.—The Swedish Budget for 1911 provides for additional expenditure on railway and canal works, and £80,000 for electricity works at Trollhättan.

Underground Telegraph Cables.—At Wednesday's meeting of Newcastle-on-Tyne Chamber of Commerce it was stated that the Postmaster-General had intimated that provision would be made in this year's estimates for the completion of the underground lines between Leeds and Stockton. This would complete the underground connection between Newcastle and London.

Walthamstow.—The electricity undertaking is to pay £300 per annum and the tramway undertaking £100 per annum towards the establishment expenses of the Council.

Warrington.—At the meeting of the Corporation on Tuesday Ald. Smethurst announced that the net profits on the electricity undertaking for the past year had been £1,691, against £943 for 1908-9, and on the tramways undertaking £2,750, against £2,307.

The salaries of several officials were increased, including that of Mr. F. V. L. Matthias, chief electrical engineer, from £350 to £400.

Wigan.—The L.G. Board have informed the Council that, in regard to their recent application for sanction to borrow £36,000 for the electricity undertaking, the Board will raise no objection to the Council commencing the works at once.

Wireless Telegraph Notes.—The German Government has established wireless telegraphic communication between Palm Island and Yap Island, one of the Carolines, situate 70 miles north of New Guinea.

The Hawaiian Islands have now been completely linked up with wireless telegraphy, the system employed being described as a composite one, chiefly of the "Massie" type. The day range of the principal station at Kahuku is 400 miles, and the night range is said to be 1,250 miles. The station is reported by the operating company (the Mutual Telephone Co.) to be in frequent communication at night with Sitka (Alaska), a distance of over 2,000 miles.

The Allan liner "Carthaginian" reached the Clyde on Saturday last in tow of the "Hesperian." The "Carthaginian" had broken

Digitized by Google

down 235 miles west of Malin Head. She was fitted with wireless, and her message for assistance was picked up by her companion liner, the "Hesperian." The former vessel had 800 emigrants on board. Mr. E. Dexter was the Marconi operator on the "Carthaginian," and reported that in boisterous weather there was a mishap to the machinery which left the vessel helpless. The "Hesperian" picked up her message five hours after the mishap. Mr. Sutherland is the operator on the "Hesperian."

According to the Paris "Matin" it is intended to instal wireless telegraphy at several important port stations in French West Africa with the view of connecting up the interior of the country. At Timbuctoo (according to the same authority) a station is to be erected to enable communication with Oran and Bizerta, and to form a base for radio-telegraphic communication across the Sahara.

Another report states that a wireless station has been established at Port Etienne and Dakar, and that communication has already been opened with Oran and Bizerta, the work having been largely due to Commandant Ferrie, Director of Military Telegraphs at the Eiffel Tower, Paris.

Workhouse Lighting.—The L.G. Board have authorised Belfast Guardians to borrow £6,000 for electric lighting plant.

York.—The City electrical engineer (Mr. J. W. Hame) has also been appointed tramways manager at an additional salary of £100 a year.

Electrical Engineers (London Division) Annual Sports.—The Corps of the Electrical Engineers, London Division (T) will decide their Corps trials and Championships at the London County Athletic Grounds, Herne Hill, on Wednesday, May 25, commencing at 6:30 p.m. The following are the events:—100 yds., 440 yds., 880 yds., and 1 mile running; ¼ mile, 1 mile and 5 mile cycling; 120 yds. hurdles; long jump; high jump, and inter company tug-o'-war. Quartermaster-Sergt. G. A. Applebee is the secretary of the committee in charge of the arrangements.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

The Corporation of the City of LONDONDERRY invite tenders for supply, delivery and erection of a 400 kw. mixed-pressure d.-c. turbo-generator, condenser, pipe work, floor plates, &c., switchboard panels, instruments and connections, economiser, dampers, pipes, valves, &c., and feeder cable, connections, &c. Specifications, &c., from the city electrical engineer, Mr. R. V. Macrory. Tenders to be addressed to the Town Clerk, Municipal Offices, Londonderry, by May 21. See also an advertisement.

The Tramways and Electricity committee of BELFAST Corporation invite tenders for motor boosters and switchgear and extension of lighting switchboard. Specifications, &c., from the city electrical engineeri Mr. Thos. W. Bloxam, M.I.E.E. Tenders to the Town Clerk, City Hall, Belfast, by 10 a.m. May 23. See also an advertisement.

St. Pancras (London) Borough Council invite tenders for supplying 21 flame arc lamps with 20 suitable iron cradles. Copies of specification, conditions of contract and form of tender from the electricity department offices, 57, Pratt-street, Camden Town, N.W. Tenders to the town clerk (Mr. C. H. F. Barrett) Town Hall, Pancras-road, London, N.W., by noon Monday, May 23. See also an advertisement.

SOUTHAMPTON Corporation invite tenders for supply of a 1,000 kw. steam generator, boiler, alternator and motor alternator. Particulars, specifications and forms of tender from the borough electrical engineer, Mr. H. F. Street, electricity works, Western Shore, Southampton. Tenders to the town clerk, Mr. R. R. Linthorne, Municipal Offices, Southampton, by May 24. See also an advertisement.

The Lighting committee of DUBLIN Corporation invite tenders for supply and erection of flame arc lamps and arc lamp pillars. Specifications, &c., from the city electrical engineer, Mr. Mark Ruddle, Fleet-street, Dublin. Tenders, addressed to the Chairman of the Lighting committee, 3, Cork-hill, Dublin, not later than May 20. See also an advertisement.

Tenders are invited up to June 14 for supply of 100 party line common battery telephone wall sets, 10 party line common battery table sets, 100 switches, common battery, single extension and intercommunication, and 3,000 telephone protectors to the Postmaster-General's department in VICTORIA. Tender forms and specification at the Commonwealth office, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to June 7 for supply of one frame, main distributing, to the Postmaster-General's department in WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W. See also an advertisement.

LEICESTER Tramways committee want tenders for supply of mixed pressure steam turbine direct-coupled to 750 kw. d.c. generator, with condensing plant, switchboard, &c., and two Lancashire boilers, with fuel economiser, piping, &c. Forms of tender from the Tramway Engineer, Belgrave-road, Leicester.

BRAY (co. Wicklow) Council want tenders by May 9 for supply of 330 yds. $\frac{7}{16}$ concentric paper-insulated lead-covered steel-armoured cable and 65 a.c. single-phase electricity meters. Specifications, &c., from the Electrical Engineer.

The Commissioners of H.M. Works and Public Buildings require tenders by May 19 for the erection of a telephone exchange at Cubie-street, GLASGOW. Forms of tender, &c., from the Clerk of Works, Head Post Office, Glasgow.

BECKENHAM Council require tenders by 4 p.m. May 23 for wiring work, including canvassing, and (alternatively) for wiring only. Specifications, &c., from the Resident Engineer, Electricity Works, Beckenham.

WALLASEY Council want tenders by May 30 for two years' supply of a.c. transformers. Specifications from the Electrical Engineer, Seaview-road, Liscard.

METROPOLITAN ASYLUMS BOARD want tenders by 10 a.m. May 11 for supply of electrical accessories, ironmongery, &c. Forms of tender from the Board's Offices.

MANCHESTER Tramways committee want tenders by 10 a.m. May 10 for supply of steel tie-bars for tramrails. Specifications from the tramways manager.

ECCLES Electricity committee invite tenders by 10 a.m. May 12 for supply of 2,000 yds. h.t. concentric paper-insulated cable. Particulars from the Borough Electrical Engineer.

RADCLIFFE Council want tenders by May 14 for supply and erection of a 300 kw. c.c. dynamo. Specification, &c., from the engineer.

Tenders are invited (up to May 17) for supply to the Postmaster-General's Department, VICTORIA, of 50 coin attachments. Tender forms and specifications from the High Commissioner's Office, 72, Victoria-street, London, S.W.

The Postmaster-General of the Commonwealth of AUSTRALIA requires tenders up to May 17 for supply of 2 tons of wire, twisted pair, outside distributing, No. 16 Legal S.W. gauge. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W.

Tenders are invited up to June 8 for the supply of protectors, switchboards (small) and common battery telephones to the Postmaster-General's Department, QUEENSLAND. Tender forms, specifications and general conditions may be obtained at the Commonwealth offices, 72, Victoria-street, London, S.W.

Tenders are required by June 8, 1910, for the supply of six sections of common battery switchboard and equipment, jumper wire and cable to the Postmaster-General's department in QUEENSLAND. Tender forms and specifications from the Commonwealth office, 72, Victoria-street, London, S.W.

Digitized by Google

Tenders are invited, up to May 18, for the supply of paper insulated lead-covered and brass ribbon taped cable to the Postmaster-General's Department in QUEENSLAND. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to June 1, for the supply of eight sections of common battery switchboard to the Postmaster-General's Department, NEW SOUTH WALES. Tender forms, specifications, and general conditions may be obtained at the Commonwealth offices, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, MELBOURNE (Victoria) wants tenders by May 24 for supply of six miles of lead-covered paper-insulated screened 50-conductor telegraph cable, and by June 14 (fresh tenders) for subscribers' equipment for Hawthorn Telephone Exchange.

Australasia.—A Wellington (N.Z.) firm desire to obtain quotations, from British manufacturers, for solid drawn steel conduit and fittings, screwed with standard gas thread, and for insulated cable, made by a firm belonging to the Cable Makers' Association, or equal thereto, and another Wellington firm wish to hear from makers of all kinds of electric cable. Catalogues, with information as to discounts, &c. (quoting preferable c.i.f. and e.), to H.M. Trade Commissioner, 9, Grey-street, Wellington.

TENDERS RECEIVED AND ACCEPTED.

At the meeting of Manchester Corporation on Wednesday, the chairman of the Electricity committee (Mr. Howarth) stated that the committee had accepted a tender from a Milan firm (through the General Electric Co.) for the supply of l.t. house service cable.

He said that the English prices asked were from 3s. 1¼d. to 3s. 6d., against 2s. 3¾d. by the Milan people. He suggested that there was a combination among British manufacturers which had the effect of raising and maintaining prices, and by letting that contract the committee saved £158.

Objection was taken to the acceptance of the contract as contrary to the standing orders, seeing that the Council had no knowledge of the hours of work, rate of wages and conditions of labour in Milan. It was proposed to refer the matter back to the committee, but this was rejected by 40 votes to 29.

St Pancras (London) Council have received the following tenders for the supply of open-type arc lamp carbons:—

Sloan Electrical Co. ..	£687	15	0	Siemens Bros. Dynamo Works	1,279	8	11
W. Giepel & Co.	744	2	6	Sirius-Werke A.-G....	1,386	0	0
H. G. Mayer & Co. ...	756	0	0	Johnson & Phillips (samples not submitted)	777	0	0
Crompton & Co.	763	14	9				
Ship Carbons (Ltd.)).	774	10	3				
G. Braulik	813	15	0				
General Electric Co. ..	922	18	0				

Nuneaton Corporation have received the following tenders for a water-tube boiler and a feed pump:—

Boiler.

Edwin Danks & Co. (*accptd.*)..	**£710**	Brightside Foundry & Eng.Co..	£925
Babcock & Wilcox.....	715	Clarke, Chapman & Co.	997
Hawksley, Wild & Co.	795		

Feed Pump.

F. Friedenthal (*accptd.*)	**£90 & 109**	J. P. Hall & Sons.....	£141 & 163
Edwin Danks & Co.	£106 & 132	Lee, Howl & Co.	143
John Spencer (Ltd.).....	108	Brightside Foundry & Eng. Co.	144
J. Reynolds & Co.....£108 & 126		Hawksley, Wild & Co.	160
Hayward, Tyler & Co....£110 & 120		Clarke, Chapman & Co.	213
Babcock & Wilcox	135		

Salford Council have accepted the following tenders for annual stores for the electricity department:—

W. Turner (Ardwick) Ltd., asphalte bridges; Cowans (Ltd.), circuit-breakers; Electrical Co., switches and cut-outs; W. T. Glover & Co., bitumen cables and bare copper stranded wire; H. R. Mansfield, stoneware conduits; Albion Clay Co., stoneware conduits and stoneware pipes; John Bassett, tinned copper strip; Johnson & Phillips, copper fuse wire and white tape; L. Andrew & Co., mica sheets, rubber gloves, rubber overshoes and rubber caps for cables; Veritys (Ltd.) and General Electric Co., high and low-speed motors (½ to 7½ H.P.); Electric Construction Co., high and low-speed motors (10 to 15 H.P.); Lancashire Dynamo & Motor Co., high and low-speed motors (20 to 50 H.P.); Hanchett, Barratt & Co., 12 single-phase house transformers, £5. 10s. each.

Dublin Lighting committee recommend the acceptance of the tender of the British Insulated & Helsby Cables at £17,532 for the supply of extra high-pressure and low-pressure cables for a period of two years.

Warrington Council have accepted the tender of J. Howden & Co. for a 1,000 kw. turbo-alternator at £4,255; that of the British Westinghouse Co. for a 750 kw. rotary converter at £1,850; and that of Cowans (Ltd.) for switchgear at £506. 5s.

Southampton Council have renewed the annual contracts with W. T. Glover & Co. and the Craigpark Electric Cable Co. for supply of cable.

Edinburgh Electric Lighting committee recommend acceptance of the tender of the Lahmeyer Electrical Co. for 12 months' supply M.S. metal filament lamps.

London County Council have accepted the tender of Bruce, Peebles & Co. for three-phase motors for the second section of the central car repair depot at £575.

Poplar (London) Council have accepted the tender of the Worthington Pump Co. for motor-driven feed pump at £218. 10s.

Bolton Electricity committee have accepted the tender of Ed. Beanis & Co. for mechanical stokers.

Gloucester Corporation have accepted the tender of W. Geipel & Co. for arc lamp carbons at £111. 16s. 7d.

Salford Corporation have accepted the tender of the Northern Electrical Co. for wiring the Wellington-street school at £133. 13s.

BUSINESS NOTICES.

The D.P. Battery Co. have appointed as their representatives in Argentina (Messrs. Milne, Makein y Cia., Suipacha 88, Buenos Aires), and in Turkey, Messrs. Wm. Sprowson & Son, Constantinople. The agency of the latter firm is for Turkey, Greece and the Balkans.

Mr. Chas. E. Gunner, who has been so long identified with conduit practice both with the G.E.C. and latterly with Simplex Conduit (Ltd.), has severed his connection with the latter firm, and is now engaged in perfecting a number of improvements relating to conduit and installation practice generally, of which we hope to give particulars in an early issue.

Messrs. Davies & Ransome, Caxton House, Westminster, have been appointed sale agents in London and the South of England for the Buffoline Noiseless Gear Co.

Mr. Thomas W. How, managing director of the Empire Roller Bearings Co., has been appointed managing and consulting director of the Horsfall Destructor Co., Pershore, in succession to the late Mr. Arthur Greenwood. The business of both companies will be directed from the London address, 15, Victoria-street.

Messrs. D. H. Bonnella & Son have taken over the agency for M. S. metal filament lamps.

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by public auction at the Royal Arsenal, Woolwich, on May 19 (by order of the Secretary for War) some unserviceable and obsolete stores, including quantities of iron, steel, copper, gunmetal, lead, bronze, &c., also lathes, machine tools, electric cable, telegraph instruments, electric lamps, &c. May be viewed on Tuesday and Wednesday previous to and on morning of sale. Catalogues from the War Office, Whitehall, the Ordnance Office, Tower, and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Plant for Sale.—Eastbourne Corporation advertise for sale a 50 kw. steam alternator. Particulars from the borough electrcial engineer, Mr. J. K. Brydges.

Electric Supply Publicity.—In our issue of Feb. 25 we described a poster which was being issued by the electric light companies in London with a view to inducing the public at large to more fully appreciate the value of electricity for domestic purposes. This showed the portion of London visible from the neighbourhood of the Houses of Parliament illuminated by a gigantic glow lamp. We have now received from the committee which is dealing with this publicity work a reproduction of this illumination in card form, suitable for hanging in a show-room or shop window. As before, space is left for the insertion of the name of a supply authority.

Whitsuntide Holidays.—The countryside is looking its best, and the facilities offered by the railway companies for visiting the charming rural spots which abound on most routes out of London and the other cities and towns of England have been greatly extended this year, and comfortable and expeditious travel has been well provided for. We have seen several of the printed booklets containing the arrangements for the holidays, and amongst these is the "A.B.C. Programmes" issued by the Great Central Railway Co. There are over 300 seaside and inland health resorts in the Midlands and the North which can be reached in quick time at very low fares, and the choice of destination stretches away up to the far north of Scotland. Nearer London the Vale of Aylesbury, the Chiltern Hills and Stratford-on-Avon should particularly appeal to rest and holiday seekers. Express corridor trains with buffet car accommodation leave Marylebone at suitable times on Friday, Saturday, Sunday and Monday, May 13, 14, 15 and 16, and full particulars of times of departure, fares and other information are contained in the programme under notice, which may be obtained free at Marylebone Station, from any of the Company's town offices and agencies, or by post from the Publicity department, 216, Marylebone-road, N.W.

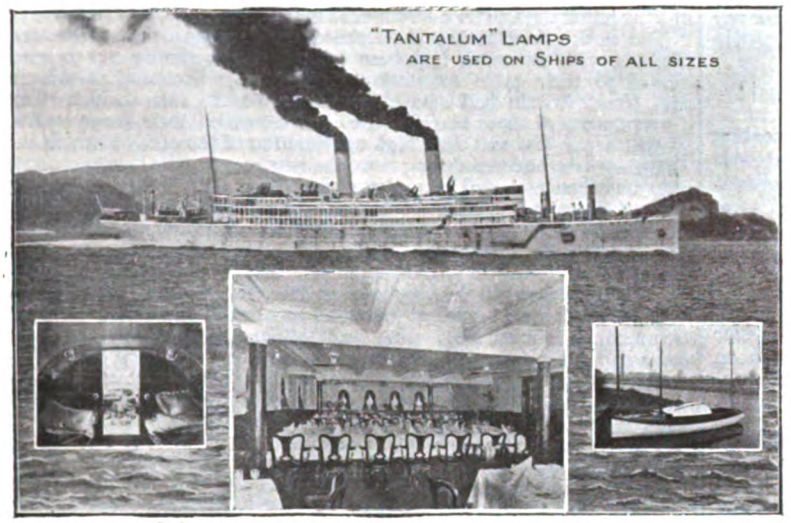
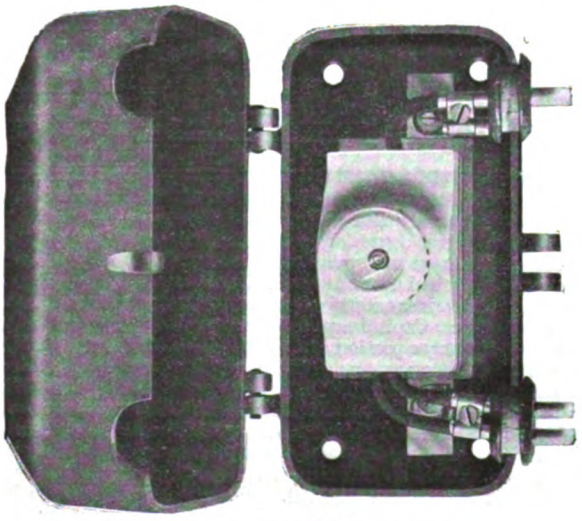
Tantalum Lamps for Ship Lighting.—Tantalum lamps are used for all classes of ship lighting, from a man-of-war to a ferry-boat. The illustration herewith shows an Atlantic liner, on which more than 1,000 Tantalums are installed, in comparison with a pleasure motor yacht. The strength of the lamp enables it to withstand the severe vibration experienced on board ship. The centre inset shows one



SHIP-LIGHTING "TANTALUMS."

of the handsome interiors to be found on the larger types of vessel. Messrs. Siemens Bros., the manufacturers of the Tantalum lamp, make a speciality of electric light fittings for ship and yacht lighting, and all interested in that class of work should obtain particulars and prices when considering new installations.

Concentric Wiring on the O.S. System.—Messrs. Siemens Brothers & Co., Caxton House, Westminster, S.W., have sent us a copy of their new catalogue A 517 (supplementary to No. 517), in which the advantages of the O.S. Wiring System for concentric purposes are described. Messrs. Siemens Brothers claim that the O.S. system, when employed for concentric wiring in any combination of its two component parts, effects a saving in the cost of materials and labour, which may reach as high as 40 per cent. Besides the general features of the system, the advantages of low voltage are explained in the catalogue. It is shown how the consumer can save in current and outlay on lamps by using low voltage Tantalum lamps, and, in connection with alternating current supplies, by installing a double-wound transformer. The latter apparatus are listed in convenient



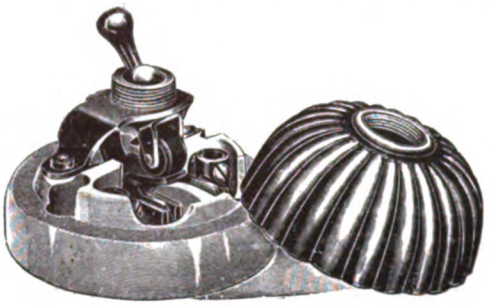
"STANNOS" HOUSE FUSE BOX.

form and sizes, from 250/5,000 watts, and for secondary pressures from 20/230 volts; the approximate number of Tantalum lamps of various candle-powers being shown, which can be connected to various listed pressures.

A novelty is the "Stannos" House Fuse Box, illustrated herewith, which is employed where "Stannos" wires, run on the concentric system, are used for the purpose of supplying separate houses, outbuildings, &c. (as in the case of the Fixed Price Light Co.'s system). The box consists of a small cast-iron case with hinged lid, containing a Siemens "Zed" cartridge fuse with non-interchangeable cartridge, and the sheathings of the "Stannos" wires are clamped at each entry to the iron case, the two clamps being bonded together. A small window is provided in the lid of the box to enable the fuse to be inspected without unsealing the case.

In addition the catalogue contains prices and particulars of "Stannos" wires for concentric purposes, Tantalum lamps, and general instructions for concentric wiring on the O.S. System. It is of interest to point out that "Stannos" wires are now being made in the following sizes: 1/18, 1/16, 3/20, 7/20, 7/18 and 7/16.

Tumbler Switches.—The accompanying illustration shows a new tumbler switch put on the market by Messrs. Marsh, Son & Co. It has been designed with a



[NEW FORM OF TUMBLER SWITCH.

very large break and all the metal parts are quite heavy enough to carry considerably more current than the 10 amperes for which it is designed. The make-and-break are very quick and the live parts are well protected. Arrangements have been provided to allow the switch to be used on looping-in systems.

CATALOGUES, &c.

AMPERE CELL.—Messrs. D. H. Bonnella & Son have issued a pamphlet dealing with the "Ampere" cell, whose large output of 5 amperes admirably adapts it for use in telephone, experimental and medical work. The cell is composed of a specially prepared compressed carbon block, carefully wrapped in cloth, a cylindrical zinc with lead connector and a circular glass jar of special design with a papier-maché cover.

ST. HELENS CABLE.—The St. Helens Cable & Rubber Co. have ready a small catalogue in which are arranged card illustrations and details of various equipment supplied by the company. These include cables and wires of all kinds and rubber goods generally.

SUNDRY INDIARUBBER GOODS.—We have received from the India Rubber, Gutta Percha & Telegraph Works Co. a copy of their latest list dealing with mechanical and sundry indiarubber goods. These include such articles as indiarubber sheets, hose of all kinds, gloves, corks, door-stops and many other useful articles and apparatus.

EDISWAN FITTINGS.—The Edison & Swan Co.'s latest catalogue deals with shop, factory, colliery, street and traction fittings. A glance through this catalogue shows a wide field of goods which this company are able to turn out, covering a good range of "everybody's requirements."

A.E.G. APPARATUS.—From the Allgemeine Elektricitäts-Gesellschaft come three pamphlets dealing respectively with the generating stations at Besswitz, an automatic electrically-worked pump for house supply work, and a new controller. The station described in the first pamphlet is intended for the supply of energy to farmers and other agricultural workers.

CROMPTON INSTRUMENTS.—Messrs. Crompton & Co. have completed a catalogue which deals with electrical instruments of the moving coil type for continuous-current work. In this are illustrated and described the many patterns of this taype made by the firm. The list should be in the hands of all electrical engineers and contractors.

FERRANTI TWO-RATE METER.—Messrs. Ferranti Limited have issued a pamphlet dealing with a new two-rate meter recently designed by them. This instrument is described at some length on another page of our current issue.

HENLEY'S FLEXIBLE CABLES.—We have received from Messrs. W. T. Henley's Telegraph Works Co. a list describing their twin flexible cables, which are provided with an earthing core in compliance with Home Office Regulations. They are made in two types, C.M.A. flexible and standard flexible, the former being composed of high conductivity 36 S.W.G. wires insulated with pure vulcanised

Digitized by Google

indiarubber and taped. The earthing conductor is composed of copper wire of the same size braided with cotton and compounded. The three cores are made up together circular with jute wormings strongly braided and served over all with preservative compound. The insulation resistance of such a flexible is 600 megohms per mile at 60 deg. after 24 hours' immersion in water.

JAHNS GOVERNOR.—Messrs. Jens Orten-Böving & Co. are issuing a catalogue on this subject which describes a governor suitable for use in governing turbines and engines very closely, in accordance with the present requirements.

BANKRUPTCIES, LIQUIDATIONS, &c.

At the London Bankruptcy Court on Wednesday the first meeting of creditors took place of Samuel Walter Hart, inventor and patentee of the Hart accumulator. Debtor attributed his failure to depreciation in value of his shares and other property. Liabilities were £3,000, but he claimed that the assets should exceed these when realised. In the absence of an offer, the Official Receiver was left in charge of the estate under an administration in bankruptcy.

The first meeting of creditors of Robt. E. Joy (trading as the Bristol Electrical Co.), 143, Cheltenham-road, Bristol, will take place on May 11, at 26, Baldwin-street, and the public examination on May 13 at the Guildhall, Bristol.

A receiving order has been made against John Filmer Davie, electrician, late of 10, Gt. Castle-street, London, W. First meeting of creditors May 10 at Bankruptcy-buildings, London, W.C., public examination at same place on June 8.

The Electric Conversion Synd. (Ltd.) is being wound up voluntarily. Mr. F. S. Salaman, 1, Oxford-court, Cannon-street, London, E.C. is liquidator. Meeting of creditors at same address on May 9.

The Davey Electric Co. (Ltd.) is being wound up voluntarily. Claims to Mr. J. Andrews, 20, North John-street, Liverpool, by June 9. A meeting of creditors will be held at 112, Whitechapel, Liverpool, on May 17.

COMPANIES' MEETINGS AND REPORTS.

Great Northern Telegraph Co. (Ltd.)

At the meeting held on April 30 at Copenhagen the chairman (Commodore E. Suenson, D.R.N.), in rendering an account of the working of the company during 1909, said the company's cables again suffered rather severely from interruptions. In Europe there had been 23 on seven cables and in the Far East 21 on five cables, without reckoning those on the cables in the Yangtze river and its tributary, the Whangpoo, where the regulation of the navigable channel near the Woosung bar had caused numerous interruptions and difficulties. The cable repairs and renewals had kept their cable steamers occupied: the "H. C. Orsted" in Europe for 142 days and the "Store Nordiske" and the "Pacific" in the Far East for 260 days, of which 15 in Europe and 78 in the Far East were for other administrations. The landlines via Kiachta and via Wladiwostock across Russia and Siberia connecting their two submarine systems, the one in Europe and the other in the Far East, had more and more won favour with the telegraphing public. Notwithstanding the appreciable decrease in traffic between Europe and the Far East, the amount of traffic passing over the company's routes had decidedly increased. On Oct. 1 last the same reduced rate as that via India was introduced by both routes via Russia for press telegrams between Europe and the Far East. The reductions in the European rates (adopted by the International Telegraph Conference at Lisbon in 1908) had been in force since July 1 last. These reductions, in conjunction with those of the local rates in the Far East (mentioned last year) and the general depression in commerce and shipping in 1909 had seriously affected their traffic receipts. The decrease had, however, been counterbalanced by increased receipts from the company's participation in other telegraphic undertakings and particularly by a profit on exchange of £4,700 in 1909, compared with a loss on exchange of about £15,300 in the previous year. Their receipts from "sundries" had also been higher, and it was due to those fortunate circumstances that the board felt justified in proposing the same total dividend as for 1908, viz., 18 per cent.

In spite of the continued progress of wireless telegraphy in the field naturally belonging to it (communication from ship to ship, between ship and shore or shore and small islands, and for strategical purposes) the year had not, as far as they knew, witnessed the establishment of any new wireless connection of importance competing with the telegraph by wire, although several such connections had been projected. The company had, nevertheless, acquired the exclusive right of using between several countries certain patents for wireless telegraphy, for which they had been in negotiation for some years past. In taking that precaution the board had, however, been prompted mainly by its desire to meet the repeated wishes of many shareholders. It was evident that in a field where the practical application of a discovery, although showing remarkable progress, was still as much in its infancy as that of wireless telegraphy, inventions of one day were liable to be out-distanced on the next day, that the possession of a patent of an invention did not confer the right to use it in the absence of concessions to that effect from the interested governments, and, finally, that the exploitation of wireless telegraphy had hitherto not proved remunerative except, as they sincerely hoped, to the inventors, who had certainly deserved a substantial reward for their marvellous inventions and their arduous labours. If they had acceded to the wishes of some shareholders it was due to a desire to reassure them and to provide as far as possible against all contingencies rather than to their being actually convinced of the utility of the invention outside its own particular field.

The notice terminating their concession for the cable connecting Norway with Denmark had been followed by a similar notice with regard to their cable connecting Norway with Scotland. Denmark and Great Britain had also given notice for the same cables. The Governments of these two countries had expressed their sincere regret at that separation and their high appreciation of the services which the company had rendered during more than 40 years. The fact that those two Governments, and also those of Sweden and Russia, had been pleased to extend all their other concessions in those countries, was the best proof of the sincerity of those assurances. The Norwegian Government, acting in accord with the other interested Governments, had expressed its desire to purchase the two cables in question, the cable landed at Arendal in Norway and at Hirtshals in Denmark, 69 n.m. long, and the cable landed at Egersund in Norway and at Peterhead in Scotland, 272 n.m. long. The negotiations regarding the purchase price had not yet terminated, but the price would be based exclusively on the actual technical value of the cables, without any addition for goodwill. The loss did not affect their general system; their universal system, extending from the West of Europe to the East of Asia, would remain intact. The company's negotiations with Japan regarding their future relations with that Empire after the expiration of their exclusive privileges at the end of 1912 had not been resumed during the past year because the Imperial Government had not expressed any desire to that effect. It might be mentioned that the company enjoy in Japan the same right as they possess in several other countries connected by their cables to continue working in connection with the Government lines after the expiration of their exclusive privileges. Japan did not, therefore, run any risk of becoming suddenly deprived of the use of the Great Northern cables. The fact of these cables being private and neutral property had been of great value to Japan, and it was partly due thereto that during the last wars of that Empire they remained unmolested and that Japan was able to maintain telegraphic communication with the whole world. If they had been Government-owned cables belonging to one of the belligerent powers they would have been legitimate booty for the other, even if it had not had command of the sea. Any hostile power, strong or weak, will easily find means of cutting or destroying a submarine cable, if such an act be considered legitimate, but will hesitate if by doing so it lays itself open to just reproaches for destroying private and neutral property and to claims for compensation. This consideration had probably, amongst others, induced the great maritime powers as Great Britain, Germany, France and the United States, to adopt the principle of leaving their international submarine connections to private enterprise and exploitation, particularly where they form part of a universal system such as the Great Northern.

Their traffic receipts, &c., had increased by about £9,600, owing to the circumstances previously mentioned, and sundries by about £2,760. Salaries and wages had decreased by £5,380, expenses of stations, offices and agencies had increased by £430; ordinary supervision, &c., of lines and repairing steamers by about £2,640; instruments and cells by £480; maintenance of buildings by £1,600, on account of the installation of new offices in London; sundries by about £1,100. Rates and taxes were less by £720; travelling expenses by £190, and bank commisison, &c., by £100, thus making the total decrease of expenses about £170.

AUCKLAND ELECTRIC TRAMWAYS CO. (LTD.)—The chairman (Mr. C. G. Tegetmeier) stated at the meeting on Monday that the results of the past year showed steady and progressive business.. Out of the profits they had set aside for depreciation £15,000, compared with £12,500 in 1908. Expenditure on renewals and reconstructions would vary from year to year. They had over 22 route miles of track, and they had to look forward to the time when extensive reconstructions of the permanent way would be necessary. Capital expenditure showed an increase for the year of £56,601. The larger portion of that was for additions to their power station and distributing system. The new 600 kw. set that had been installed during the year brought the capacity of their plant to 2,725 kw. The expenditure also included the enlargement of the power sheds and repair shops and the cost of five new cars. Eight more cars are in course of construction, bringing the total stock of cars to 100. They carried 28,736,000 passengers, an increase of 2,592,000, and the passenger receipts show an increase of £16,538. Working expenses were heavier owing to increased car-mileage and to higher scale of wages paid to the employés. Repairs and maintenance cost £30,153, an increase of £4,073. A dividend of 6 per cent. per annum was paid on the ordinary shares.

BRITISH WESTINGHOUSE ELECTRIC & MFG. CO. (LTD.)—The directors, in their report for 1909, state that, notwithstanding serious trade depression, accompanied by unusually severe competition, they can report an improvement in results of the year's trading. Trading profits were £84,156, from which have to be deducted depreciation on machinery, plant, &c., £6,480 (in addition to £10,262 reserved for general depreciation), expenses on surplus land and buildings (£5,673), interest on 6 per cent. prior lien debenture (£14,700), interest on 4 per cent. mortgage debenture stock (£49,654), leaving £7,647. This balance has been ab-

Digitized by Google

sorbed by the appropriation of £5,300 required for the prior lien redemption fund, expenditure on contracts of previous years (£2,485), and by writing off £660 from expenses of prior lien debentures issue, leaving a debit balance of £798. This, with the debit balance of £6,521 brought forward, makes £7,319, and is now carried forward. In addition to a substantial sum appropriated out of revenue during the year for maintenance of buildings, machinery and plant, a further £16,742 has been applied to depreciation of these items. While there has been a smaller output for the home market the export business shows an appreciable improvement. Mr. P. A. Lange, general manager of the works, has been elected to a seat on the board.

BROMLEY (KENT) ELECTRIC LIGHT & POWER CO. (LTD.)—At the recent meeting Mr. F. E. Gripper said that the company had had a very satisfactory year. The lamp connections had increased substantially, and, notwithstanding the introduction of the metal filament lamp, their receipts from sale of current had not fallen off. The rateable value of the undertaking under the new assessment had been very nearly doubled, but they had appealed and got it very largely reduced. The directors proposed to pay 7 per cent. for the second half of the year (making 5½ per cent. for the year), the same as in 1908.

CITY OF SANTOS IMPROVEMENTS CO. (LTD.)—Mr. D. M. Fox announced at the meeting last week that, including the San Vincente line, about 15 miles of railway and tramway had been electrified, and there remained about 15 miles to be converted. In spite of the wish of the inhabitants of Santos and San Vincente to have the remainder of the system electrified, and notwithstanding the efforts of the directors to induce the Camara to come to terms, no definite contract had yer been entered into.

DEUTSCH SÜDAMERIKANISCHE TELEGRAPHENGESELLSCHAFT, A.G.—From Aug. 26 to Dec. 31, 1909, this company made a net profit of M.187,623 (£9,481) and a dividend of 6 per cent. is to be paid. The cable of the company has been working only between Borkum and Teneriffe until the second portion—Teneriffe to Monrovia—was opened a few weeks ago. The final portion—Monrovia to Pernambuco—is expected to be finished by March next. The cost of construction has been covered by the issue of M.6,000,000 of new shares and M.9,850,000 of 4½ per cent. debentures.

EASTERN TELEGRAPH CO. (LTD.)—The directors' report for the six months ended December 31, 1909, states that the revenue amounted to £620,942. 4s. 1d., from which are deducted £204,871. 2s. 10d. ordinary expenses and £45,667. 12s. 6d. expenditure relating to maintenance of cables, sundry differences in exchange and income tax payable abroad, leaving £370,403. 8s. 9d., to which is added £55,068. 15s. 11d. brought forward, making a total available balance of £425,472. 4s. 8d. After providing for income tax payable in England, interest on mortgage debenture stock and dividends on preference stock, which together absorb £81,019. 7s. 6d., there remains a balance of £344,452. 17s. 2d., out of which the directors have placed £130,000 to general reserve and have paid an interim dividend of 1¼ per cent. on the ordinary stock, amounting to £50,000. The directors now recommend the declaration of a final dividend on the ordinary stock of 1¼ per cent. and a bonus of 2 per cent., amounting together to £130,000, both payable on May 11, tax free, and making, with the three previous payments on account, a total distribution of 7 per cent. for the year 1909. It is proposed to carry forward the balance of £34,452. 17s. 2d. The company, in combination with the Associated Companies, has made arrangements for the transmission of a special service of British Imperial news, available for distribution throughout the British possessions served by the Associated Companies, whereby a considerable addition to the volume of Imperial news is being provided without any increase of cost to the public.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.) The report of the directors for the half-year ended Dec. 31 states that the gross receipts amounted to £315,034. 18s. 7d., against £306,889. 10s. 7d. for the corresponding half-year of 1908. Working expenses, including £17,997. 0s. 10d. for maintenance of cables, absorb £143,674. 0s. 4d. against £151,507, leaving £171,360. 18s. 3d. From this is deducted £3,841. 9s. 3d. for income-tax payable in England and £15,048 for interest on debenture stock, leaving as the net profit for the half-year £152,471. 9s. Adding £58,844. 3s. 1d. brought forward there is an available balance of £211,315. 12s. 1d. One quarterly interim dividend of 1¼ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount, making, with the interim dividends paid for the first half-year a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share (or 2 per cent.), making a total distribution of 7 per cent. for the year 1909. £50,000 has been transferred to general reserve, and the balance of £26,315. 12s. 1d. is carried forward.

ELECTRIC SUPPLY CORPORATION (LTD.)—For the year ended Dec. 31, 1909, the gross earnings were £23,801, an increase of £2,561 on 1908. The sum taken into net revenue account was £9,300, compared with £6,566. After paying interest there remains £3,780, against £2,397. The equivalent of 113,699 8 c.p. lamps is connected, against 97,778 8 c.p. in 1908; and 2,492,416 units were sold, against 2,034,087. The directors report continued and excellent progress by the Dumbarton Tramways Co. and the Hendon Electric Supply Co., the total number of lamps taking supply from the latter at Dec. 31 last being over 23,000 8 c.p., compared with 12,600 in 1908.

JOHNSON & PHILLIPS (LTD.)—For the year ended Dec. 31, 1909, the profit on trading accounts, &c., after making provision for bad and doubtful debts, and after charging to revenue upwards of £3,691 for maintenance of buildings, plant, &c., amounts to £15,359. 7s. 6d., making, with £681. 2s. brought forward, £16,040. 9s. 6d. Deducting directors', auditors' and trustees' fees (£1,503. 15s. 8d.), interest on debenture stock (£7,850. 13s.), reserve re debenture sinking fund (£5,059. 11s. 6d.), and interest on second debentures (£684. 1s. 2d.) the sum of £942. 8s. 2d. has been carried forward. The directors report that the business of the company during the year under review was adversely influenced by depression in trade throughout the country. The disinclination generally shown to place large orders, and consequent active competition, kept prices low, while the cost of raw materials ruled high. In October, the compounding shop was destroyed by fire. While the company incurred no direct loss, considerable difficulty was occasioned to the cable department, and it was necessary to equip temporary premises to avoid delay in the execution of contracts. The profit for the year shows an increase of £5,322 over the preceding year. Should the electrical trade improve, of which there seems to be some indication, the directors believe that the company is in a position to secure its full share of any business increase. The directors have appointed Mr. Walter Claude Johnson and Mr. Thomas Dence additional members of the board, and Mr. F. S. Paterson has retired.

LEWES & DISTRICT ELECTRIC SUPPLY CO. (LTD.)—For the year 1909 the revenue amounted to £2,402. 3s. 5d., an increase of £107. 8s. 7d. The expenses, including £448. 16s. for interest on temporary loans and a provision of £55 for battery renewals, amounted to £1,970. 15s. 9d., leaving a profit of £431. 7s. 8d., which, added to £33. 13s. 1d. brought forward, makes £465. 0s. 9d. The directors recommend that £450 be placed to depreciation and renewals account, and £15. 0s. 9d. carried forward. The demand for electrical energy for lighting and power continues to increase steadily, and at the end of the year the equivalent of 14,116 8 c.p. lamps (11,915 for lighting and 2,201 for power) were connected to the mains, against 12,357 8 c.p. in 1908. The 120 kw. Diesel oil generating set installed in October, 1908, has generated nearly all the units required during the year at considerably reduced cost per unit.

MUSSELBURGH & DISTRICT ELECTRIC LIGHT & TRACTION CO. (LTD.)—The balance at credit of net revenue account for the year ended Dec. 31 was £6,180. 13s. 7d., making with £131. 13s. 9d. brought forward £6,312. 7s. 4d. After deducting interest on debentures for the year (£2,501. 9s. 7d.) the balance was £3,810. 17s. 9d., of which £2,000 was placed to reserve and renewals fund, and after writing off certain items £1,255. 16s. 9d. was carried forward. Within the last two years extensions of the lighting mains to Inveresk and Levenhall have been carried out, the capital expenditure incurred having been met out of the cash resources of the company, and, as the directors do not wish to further deplete the working capital, they have decided to postpone the declaration of a dividend until the cash at their disposal warrants it. The balance of £1,255. 16s. 9d. carried forward will permit of a dividend of 2½ per cent. being paid on the preferred shares, and this they expect will be done towards the end of July. As compared with 1908, the profits (exclusive of interest, &c.) show an increase of £2,247. 12s. 1d., out of which the tramway undertaking takes credit for £1,892. 7s. 11d., and the lighting undertaking £355. 4s. 2d. The traffic revenue for the year amounted to £12,450. 8s. 9d., against £9,711. 10s. 1d., the receipts per car mile being 9·27d., compared with 8·72d., and the number of passengers carried was 2,224,024. The increased receipts are being maintained.

NEWCASTLE, EMLYN & DISTRICT ELECTRIC SUPPLY CO. (LTD.)—At the recent meeting the chairman (Dr. Powell) said that the company commenced supply in September last, and, with an increasing number of customers, it might safely be assumed that the company would soon have a balance in hand and be in a position to declare a dividend. The future prosperity of the company was assured.

PARA ELECTRIC RAILWAYS & LIGHTING CO. (LTD.)—The receipts for 1909 were £225,916, an increase of £20,605. The expenditure in Para was £120,309, against £152,637 in 1907-8, the net earnings (subject to London expenses) being £105,606, against £52,674. After providing for London expenses, debenture interest and sinking fund, the balance is £60,589, to which has to be added £9,863 brought forward, making £70,453. The dividend on the preference shares has been paid (£17,498) and the directors have added £15,000 to reserve for depreciation and renewals and £10,000 for contingencies, leaving £27,954. Out of this amount it is proposed to pay the arrears of cumulative dividends on the preference shares for 1906 and 1907, which amount to £27,000, leaving to be carried forward £954. Since Dec. 1, 1909, the receipts show an increase of £13,842, compared with the corresponding period last year.

RANGOON ELECTRIC TRAMWAY & SUPPLY CO. (LTD.)—The directors' report for the year 1909 states that owing to the increasing demand for energy it has been decided to extend the power station and to instal an additional 2,500 kw. turbine, thereby increasing the capacity of the station to 5,000 kw. In comparison with 1908, the traffic receipts for 1909 increased by over 15 per cent., and the traffics so far received for the current year show further steady growth. The receipts from the private lighting and power department have doubled those of 1908, and a further substantial increase is looked for during the present year. The gross profits for the year amounted to £42,170. 8s. 5d., and with interest, &c., £42,225. 1s. Deducting Liverpool office expenses (£2,388. 13s. 5d.), interest on debenture stock (£7,341. 13s. 1d.), provision for redemption of debenture stock (£3,872), depreciation (£774. 17s. 4d.), and transferring to reserve £5,000, the balance was £22,847. 17s. 2d., and, with £383. 2s. 5d. forward, £23,230. 19s. 7d. The preference dividend required £15,000, and formation expenses were £2,300, leaving available £5,930. 19s. 7d., out of which the directors recommend an ordinary dividend of 3 per cent.

Digitized by Google

(tax free), requiring £5,310. 0s. 7d., leaving £620. 19s. to be carried forward.

RIVER PLATE ELECTRICITY CO. (LTD.)—After providing for administration expenses and depreciation on fixed plant, the revenue account for 1909 amounted to £37,342. 3s. 4d., debenture interest £10,000, leaving £27,342. 3s. 4d., which, with £5,623. 10s. 9d. brought forward, makes £32,965. 14s. 1d. The directors propose paying the balance preference dividend (£6,000), a dividend of 9 per cent. for the year on the ordinary shares (£10,800), placing £10,000 to general reserve and this, with other outpayments, leaves £5,140. 11s. 1d. to be carried forward. A contract has been made with La Plata Electric Tramways Co. for supply of all power required on that company's tramway system. The first section of the tramways was opened in January last, and it is expected that the remaining sections will be in service in the course of the year. The board report a steady and continuous growth of business both at La Plata and Tucuman. The futher business offering and the necessity of maintaining the existing services at a high state of efficiency have required the immediate provision of a large extension of the generating plant and installations in La Plata city and Ensenada port, and with this view a suitable riverside site has been acquired. This station will be equipped with two 1,500 kw. steam turbo-alternators, to be in service in time for the lighting season of 1911. The progress at Tucuman has also necessitated the provision of additional plant and mains.

SINGAPORE ELECTRIC TRAMWAYS (LTD.)—The report for 1909 states that the excess of revenue over expenditure was £28,511, against which has been charged interest, depreciation and royalty (£28,376), leaving a profit of £134. As compared with 1908 the revenue showed an increase of $17,194, the passengers carried an increase of 13,806, and the car-miles run an increase of 193,354. Notwithstanding increased car-mileage the working expenses showed a decrease of $5,258. Trade in Singapore was improving, and it was anticipated that increased traffic receipts would result. The revenue from lighting and power supplies continued to increase satisfactorily, being 62 per cent. higher than in 1908 and 216 per cent. higher than in 1907.

SOUTH METROPOLITAN ELECTRIC TRAMWAYS & LIGHTING CO. (LTD.) At the meeting last week Mr. C. G. Tegetmeier said their tramway receipts had been adversely affected by the weather. The electric lighting department had shown satisfactory increase. With the increasing use of metal filament lamps the directors had increased, as from October last, the price of current for lighting by ½d. per unit.

SUBMARINE CABLES TRUST.—For the year ended April 15 the revenue amounted to £25,259. 18s. 1d. and the expenses to £1,160. 0s. 6d., leaving £24,099. 17s. 7d., to which is added £228. 8s. 4d. brought forward, making an available balance of £24,328. 5s. 11d. After providing £17,952 to meet payment of coupons, £6,201. 1s. has been transferred to redemption fund, leaving £175. 4s. 11d. to be carried forward. During the year 52 certificates have been redeemed by purchase in the open market with the surplus funds of the trust, costing £6,201. 1s.

URBAN ELECTRIC SUPPLY CO. (LTD.)—At the meeting on Wednesday the chairman, Mr. P. D. Tuckett, said that this was the last year of the guarantee, and for a time the ordinary shareholders might have to forego their dividend. Probably a new arrangement would be made with Edmundson's Electricity Corpn., and probably a scheme would be brought forward for writing down the capital.

WELSBACH INCANDESCENT GAS LIGHT CO. (LTD.)—The directors' report states that the continued trade depression has prejudicially affected the company's sales, and that the net profit for the year shows a decrease, and the board regret that the result of the past year's trading does not allow of any further distribution to the shareholders. As regards the ordinary shares, it is impossible, in view of existing conditions, to hold out any hope of dividends.

WEST AFRICAN TELEGRAPH CO. (LTD.)—Revenue for the year ended Dec. 31, 1909, amounted to £59,099. 8s. 10d., from which is deducted £15,737. 3s. 2d. ordinary expenses and £6,520. 16s. 3d. for expenditure relating to the maintenance of cables and income tax abroad, leaving £36,841. 9s. 5d., added £1,731. 3s. 9d. brought forward, making an available balance of £38,572. 13s. 2d. £1,406. 13s. 6d. has been provided for income tax, £27,000 has been transferred to general reserve and an interim dividend of 2 per cent. (tax free), absorbing £4,621. 16s., has been paid. The directors recommend payment of a final dividend of 2 per cent. (tax free) (making 4 per cent. for the year), £922. 7s. 8d. being carried forward.

WEST COAST OF AMERICA TELEGRAPH CO. (LTD.)—The directors' report for the year ended Dec. 31, 1909, states that the gross receipts were £50,416. 6s. 11d., against £52,612. 13s. 2d. in 1908. Working expenses were £39,204. 13s. 7d., compared with £33,193. 7s. 10d. After providing £6,000 for interest on the 4 per cent. debentures, £800 for interest on the 4 per cent. income bonds and £614. 4s. 2d. for income tax, there remains £3,797. 9s. 2d., which, added to £629. 5s. 3d. brought forward, made £4,426. 14s. 5d. £1,000 has been placed to general reserve, and the directors recommend payment of a dividend of 2½ per cent., tax free, amounting to £2,813, leaving £613. 14s. 5d. to be carried forward. The company's old cable repairing steamer "Retriever" has been sold, and replaced by a new vessel bearing the same name.

WEST INDIA & PANAMA TELEGRAPH CO. (LTD.)—The directors' report for the half-year ended Dec. 31 states that the amount to credit of revenue is £34,678. 12s. 1d., against £34,871. 14s. 5d. for the corresponding half-year of 1908, and the expenses have been £23,557. 18s. 6d., against £22,160. 3s. 3d. The balance is £11,120. 13s. 7d., to which is added £1,529. 12s. 8d. interest on investments, and £659. 15s. 2d. brought forward, making an available total of £13,310. 1s. 5d. The directors propose that this amount be dealt with by paying a dividend of 6s. per share on the first preference shares for the six months to Dec. 31 (£10,368. 18s.), and paying 9s. per share on account of dividends accrued to Dec. 31, 1909, on the second preference shares (£2,101. 1s.), leaving £840. 2s. 5d. to be carried forward. The expenses of repairing cables, charged to revenue, amount to £7,980. 14s. 7d., compared with £6,658. 12s. 1d. This is exclusive of an expenditure of £2,414. 8s. 11d., which has been charged to reserve, in respect of 33 knots of new cable used in the repair and partial renewal of the St. Kitts–Antigua, and of the Jamaica San Juan sections.

WESTERN TELEGRAPH CO. (LTD.)—The directors' report for the half-year ended Dec. 31 states that the revenue amounted to £391,504. 9s. 9d. and working expenses to £141,022. 6s. 9d. After providing £16,000 for debenture stock interest and £7,558. 4s. 7d. for income tax, there remains £226,923. 18s. 5d., or, after adding £6,463. 14s. 10d. brought forward, £233,387. 13s. 3d. First and second interim dividends, amounting to £62,379, have been paid, and after transferring £155,000 to general reserve and £10,000 to land and buildings depreciation fund, there remains £6,008. 13s. 3d., which is carried forward. The company's cable between Ascension and Buenos Aires has been successfully completed and will be opened for traffic this month.

NEW COMPANIES.

ALLEN WEST & CO. (LTD.) (108,870)—Reg. April 15, capital £20,000 in £1 shares, to carry on the business of electrical and mechanical engineers, &c. Private company. A. West is one of the first directors. Reg. office, 47, Victoria street, Westminster, S.W.

CHARLES A. DAY & CO. (LTD.) (109,249.) Reg. April 27, capital £2,000 in £1 shares, to take over the business of ironmongers and electricians carried on at Macclesfield as Charles A. Day & Co. Private company. First directors, C. A. Day and Mrs. S. Day.

DIAPANAD (LTD.) (109,209.)—Reg. April 26, capital £2,000, to carry on the business of electrical and illuminating engineers, and to acquire and turn to account a certain invention for improvements relating to illuminated signs and indicators. Private company. Reg. office, 40, High Holborn, London, W.C.

CRAMPTON & CO. (LTD.) (109,320.)—Reg. April 29, capital £2,500 in £1 shares, to carry on the business of electricians, contractors, engineers, manufacturers of and dealers in electrical apparatus, &c. Private company. First directors, W. J. Crampton, S. Crampton and E. B. Crampton.

EXPRESS CABLE INVENTIONS (LTD.) (109,071)—Reg. April 21, capital £50,000 in £1 shares, to acquire from H. Knudsen his patents and other rights in certain inventions for transmitting and receiving, photographs and printed and typewritten messages by wireless telegraphy and over cables and land lines, &c. NOTES.

Le Roi est Mort, Vive le Roi!

IT is with profound regret that we have to record the death of H.M. KING EDWARD VII. In so doing it may be remarked that we speak rather as loyal and loving subjects than as electrical engineers, for although the benefits conferred by his Majesty's actions upon the country as a whole were shared equally by engineers as by other inhabitants, his duties were too multifarious for him to pay any special attention to scientific work, or to study those engineering details which figure so largely in our daily life. The loss, both to our country and to the dominions beyond the seas, is none the less great; how great, it is too soon to tell with any certainty, nor can we tell in what abundance the seed sown by him for our good during the past few years will bear fruit.

IT would not be fitting, even in these few lines, to write of the late King without some mention of his efforts to secure permanent peace between the nations of the world. Without wishing to view this lofty ideal merely through the narrow aperture of the engineering world, it may be said that, in so doing, the King was aiding in an exceedingly direct manner the universal progress of engineering. When two nations are barbarously attacking one another with the weapons of war, neither time, money nor energy can be employed in the development of civil engineering in the true sense of the word. Forth Bridges cannot be erected, irrigation schemes cannot be perfected, scientific intercommunication must suffer, while all that is noblest in engineering is toppling to the ground through decay and the destructive efforts of the opposing forces. The longer the world remains at peace, the longer time has the engineer to perfect his theories and to develop them in practice. Engineering is really a constructive science, while war is a destructive science in every way, so that, in using his influence in favour of the former, KING EDWARD not only conferred benefits on engineering which should not lightly be forgotten, but advanced us appreciably towards that ideal when warlike weapons will be no more. During the course of his life KING EDWARD was brought into direct contact with engineering at the opening of the railway bridge across the St. Lawrence at Montreal, and at the opening of the Forth and Tower Bridges in this country. He passed through a university course in science under PLAYFAIR, and his recognition of the importance of scientific education was well indicated by his speech after laying the first stone of the new building of the Imperial College of Science and Technology at South Kensington. Finally, in founding the Order of Merit he conferred a unique honour on scientific work.

ON the purely human side of the question we may note with unqualified satisfaction that his

Digitized by Google

dealings with other nations brought him the well-merited name of "KING EDWARD, the Peacemaker," a name in which we, as a nation, should be proud to participate. Those actions by which he earned this high-sounding title have caused his loss to be felt universally, as the remarkable outbursts of sympathy with this country, which have been lately reflected in the newspapers of the world, have clearly shown during the past week. In these days of national ambitions and jealousies, when misunderstandings are liable to arise on the slightest pretext, the value of tact and diplomacy, in the best sense of the word, being concentrated in the highest personage of this kingdom is truly an attribute to be prized, and is one which we can ill afford to lose. Engineers will miss KING EDWARD'S appreciation of anything new or likely to contribute towards the welfare of his Empire. Within the last few weeks of his life he was taking a keen interest in the progress of aerial navigation, and he was among the first to appreciate the possibilities of the automobile, while it was always his practice to invite inventors to explain their apparatus to him. He thus encouraged the ingenuity of his subjects in a way which cannot be overrated.

IN offering our condolence and congratulations to his present Majesty, KING GEORGE V., we cannot but dwell upon his exceedingly difficult task in following in the steps of his father. The wide outlook that he must necessarily have obtained during his extensive travels cannot, however, but help him in this respect, and we have no doubt that his best endeavours will be to maintain the welfare of his people at the present high standard. KING GEORGE, we are proud to record, has from time to time been brought into close contact with engineering work. His naval experiences must have convinced him of the possibilities of both steam and electrical engineering, while his keen practical interest in such lowly operations as stoking cannot fail to remind us that in him we shall always have a sympathiser whose interest in our doings will not be merely theoretical. Our shortcomings also are not unknown to him, as witness his famous dictum, "Wake up, England!" on his return to this country a short time ago. His speech on that occasion might with advantage be read and re-read by those concerned with our industrial progress.

IN our late King we possessed a truly precious asset, and though, in accordance with divine dictates and human frailty, he has passed away, his place is directly taken by a worthy successor, whose loyalty to his subjects and devotion to his kingly duty cannot but accentuate our heartfelt cry: "Long live the King!"

The New London-Paris Telephone Cable.

IT may be well to state that most of the reports in the daily Press as to the results to be obtained with the new telephone cable laid across the Channel last week are very misleading. This cable has not been put down with the object of improving telephonic communication between London and Paris, but as an experiment to test the capabilities of Pupin coils under practical conditions. It is true that the normal increase in the number of telephone messages between the two countries would necessitate, sooner or later, an increase in the number of cables across the Channel, but the main object of the Post Office was to put a "loaded" cable to a practical test. The question of reducing attenuation in submarine cables is of particular importance to the Post Office at the present time, since it is wished, if possible, to obtain direct telephonic communication between London and Germany without the cables touching French or other territory. The success of the present experimental cable would, therefore, undoubtedly lead to important developments, and it may be mentioned that the French Administration intend to lay down a similar cable at an early date.

CONSIDERABLE misunderstanding also appears to exist as regards the results to be obtained with the "loaded" cable, it being stated that communication will, in future, be possible even between the Midlands and Paris. As a matter of fact, however, at the present time one can speak from Liverpool, Manchester, Leeds or Hull to Paris, and from the Midlands through to Lyons, and under favourable conditions, even from Leeds to Lyons. When the new cable is in operation the total distance over which speech will be possible will be increased by about 100 miles. In this connection it may be mentioned that by the addition of the Pupin coils the equivalent length of the new cable between Dover and Cape Grisnez has been reduced from 10·5 miles to 3·4 miles of standard cable. This is a saving of 7·1 miles of standard cable, which saving represents about 140 miles of heavy aerial telephone line, or 70 miles of ordinary telephone line, these representing, therefore, the additional distances over which telephonic communication will be possible. It must not be forgotten that the "threefold" improvement due to "loading" affects only the submarine section of the line, although some of the accounts in the daily Press would imply that the limiting distance of telephonic speech will be increased in this ratio.

Advances in Telephony.

FOR some years past it would appear that telephonic investigators have for the most part given up the attempt to obtain a substitute for carbon in the transmitter, and it has been left to Mr. S. G. BROWN to break away from the trammels of carbon and make metallic transmitters of both single and multiple contact pattern which are capable of competing with the present patterns of carbon instruments. Mr. BROWN'S most successful results have been obtained with the extremely hard alloy of osmium and iridium, and a full description of his application of hard metals to the construction of telephonic speech relays, repeaters, electrical stethoscopes and granular transmitters will be found in his I.E.E. Paper published in abstract in last week's issue

Digitized by Google

We publish this week the discussion on his Paper, from which it will be gathered that the possibilities of Mr. BROWN's new apparatus are considerable. The discussion also brought to light the fact that a great deal of work would be required before the apparatus could be considered to have entered the field of practical telephony, however immediately applicable the apparatus would be to wireless telegraphy and for medical purposes.

THAT the carbon transmitter has not by any means reached finality is well shown by the striking tests published in these columns (Nov. 19, 1909, p. 229) on the Egnér-Holmström transmitter, which demonstrate that decided improvements can be effected by suitably designing a carbon transmitter to carry a considerable current. The Shreeve repeater, which is in practical use in the United States and is the invention of an Englishman formerly with the Silvertown Company, was referred to by Messrs. KINGSBURY and COHEN, and it will be interesting to see how Mr. BROWN's repeater, when he has evolved it for both-way working, will compare with the Shreeve from the practical standpoint. The application of the repeater with metallic transmitter to the stethoscope appears to have produced a strikingly sensitive instrument which according to Dr. VOYSEY may render possible the diagnosis of certain diseases in the earlier stages. At present, however, it is a little difficult to speak with certainty as to the future of Mr. BROWN's interesting and ingenious instruments.

The Telephone as an Aid to School Management.—According to the "Electrical Review and Western Electrician" the use of the telephone in schools is becoming more and more extended. The telephone has, for instance, been found a great help to the organisation of the Williamson Free School of Mechanical Trades, where it is used for the work usually carried out by bells, speaking tubes or messengers. The Williamson school consists of thirty buildings extending over 230 acres. The telephones used are of the automatic intercommunicating type. They have become very popular, and were installed by four of the students under the direction of the Western Electric Co.

Electric Traction on the Long Island Railway.—According to the "Electric Railway Journal" the Long Island Railway has been extending its electric zone and making many expensive improvements. With the opening of the tunnels it will have for its passenger service two tunnels from Seventh-avenue and Thirty-second-street to the Sunnyside yard in Long Island City; a six-track line from Sunnyside yard to Woodside, eight tracks from Woodside to Winfield; six tracks from Winfield to Glendale Junction and Jamaica. It is estimated that there will be a saving of from 20 to 25 minutes in each direction to people living in towns on the concerned lines, over the time at present required to cross the ferry and take the tram.

Oil Consumption at the Berlin Power Station.—According to the "Electrical Review and Western Electrician," the Berlin electricity works have recently published some figures showing the saving in the cost of oil due to the displacement of reciprocating engines by steam turbines. In the fiscal year 1905-1906, when the first turbines were installed, there were required 554,514 lb. of cylinder oil and 206,373 lb. of engine oil. The output of the station for the year in question was 166,865,122 kw.-hours. In the fiscal year, 1909-1910, the output of the station was about 210,000,000 kw.-hours, but owing to the fact that the station is now operated entirely by steam turbines the consumption of cylinder oil was only 103,400 lb. and of engine oil also 103,400 lb.

Single-Phase Traction in Prussia.—According to the "Electric Railway Journal" the Prussian State Railways are preparing to equip for single-phase operation a section of steam railroad track, 18·6 miles in length, comprising the main line division between Bitterfeld and Dessau. The general design of the overhead construction and car equipment is to follow that of the Hamburg Altona line with the significant difference that the motors will be built for 15 cycles instead of 25 cycles. The power house, which will be located at Bitterfeld, is to have a two-pole 3,000 kw. turbo-alternator running at 900 revs. per min. The present electrification will cost about £96,000, and if successful will be followed by the electrification of the lines between Leipzig, Magdeburg and Halle at an additional cost of £1,300,000.

Ionisation produced by Cathode Rays ejected by X-Rays. A Paper on this subject was recently read before the Royal Society by Mr. R. D. Kleeman. The results of the author's experiments are given in the annexed table, in which are also placed the total ionisations obtained by Prof. Bragg with the α-particle. It will be seen that the two sets of values relative to air are very nearly the same. The energy spent in making an ion thus seems not to depend in any marked degree on the nature of the ionising agent.

	Cathode rays.	α particle.
Air	1·00	1·00
Carbon dioxide (CO_2)	1·08	1·08
Ethyl oxide ($C_4H_{10}O$)	1·23	1·32
Pentane (C_5H_{12})	1·31	1·35
Benzene (C_6H_6)	1·20	1·29
Ethyl chloride (C_2H_5Cl)	1·33	1·32
Chloroform ($CHCl_3$)	1·34	1·29

High-Tension Transmission Insulation.— The "Electrical World" gives an account of a suspension type of insulator for use with very high tensions. Each insulator is in two parts. The upper part is of the so-called thimble type and the lower is of the rod type, the whole forming a chain which can be extended indefinitely. The thimble shape of the insulators protects thoroughly from the weather the upper parts of the rod insulators by which spring suspension is provided. This construction gives a resiliency so that the chain of insulators is relieved in all its parts, as well as in its entirety, from the results of sudden or abrupt strains usually so destructive to mechanism of this kind. The various parts of the insulators may be detached and replaced by other parts and the total number of parts may be increased or diminished, at will, after the original structure is built. This feature is specially important in instances where after the installation of a conductor the voltage is increased.

Electric Traction on Mont Blanc.—According to "The Times Engineering Supplement," the funicular railway from Le Fayet to the summit of Mont Blanc, the first section of which was completed last July to the Col de Voza, 5,495 ft., is to be continued, and contracts have just been given out for building the second section, 7 miles in length, up to the Aiguille du Gouter, at a height of 12,000 ft. Up to a height of a little over 8,000 ft. the railway will be in the open, but from this altitude up to 12,000 ft. it will pass through tunnels. From 12,000 ft. to the summit of Mont Blanc, 15,782 ft., a tunnel will have to be driven under the glaciers in order to protect the line against avalanches; but this last portion of the line will not be constructed until the other sections are realising dividends. The cost of the line, as far as the Aiguille du Gouter, is roughly estimated at £5,000,000, and for the third short section £2,000,000. The Strub cog-wheel system is employed, and the motive power is electricity. The steepest grade will not exceed one in five, and the minimum speed will be four miles an hour. Twelve trains a day will be run to the Aiguille du Gouter, and every station will be fitted with air-tight rooms containing oxygen for travellers who may be attacked by mountain sickness.

Cable Interruptions and Repairs.

Low Cost of Electric Pumping.—According to the "Electrical Review and Western Electrician" the change-over at Wahpeton from steam to electrical operation of the city pumps has been accompanied by a great reduction in cost. Heretofore the coal alone cost £3. 12s. a day, while the electric power for running the pumps costs only £1. 5s. a day. The power is obtained from a hydroelectric plant near Fergus Falls.

Wireless in Railway Working.—The "Railway and Engineering Review" states that the Pennsylvania Railway officials are still making experiments with wireless telegraphy with a view to ascertaining its efficacy for railroad work. The mast in use for the tests is erected near Altoona, on the mountain, at a point 1,655 ft. above sea level, the receiving apparatus itself being 1,735 ft. above the level of the ocean. Communication already has been established with various wireless stations along the Atlantic coast, as well as with various vessels at sea.

Central Station Training.—It may be remembered that some years ago the Newcastle-upon-Tyne Electric Supply Co. inaugurated an "improver" system under which men who had just finished their apprenticeship were able, as Junior Assistants, to gain experience of large power supply work in the generating stations, substations and the extensive transmission and distribution systems throughout the area of this Company, and the other power companies with which they are associated. The Newcastle Company has been the nursery for central stations in all parts of the world, many of its employees having from time to time found good billets elsewhere. It is gratifying to note that the value of the experience gained in this Company's service is so fully appreciated. Only this week, by arrangement with the Newcastle Company, a considerable number of assistant engineers have sailed for South Africa to take up important positions on the staff of the Victoria Falls & Transvaal Power Co., whose chief engineer, Mr. Bernard Price, also came from the North of England. He was in fact for several years closely connected with the extension of the Newcastle Company's system.

High-Voltage Strains in Dielectrics.—At a special meeting of the Boston Section of the American Institute of Electrical Engineers held at the Massachusetts Institute of Technology, Prof. D. C. Jackson presiding, an illustrated lecture on "High-Voltage Strains in Dielectrics" was given by Mr. H. S. Osborn. The speaker emphasised the mathematical simplicity attending analyses of insulation strains in single-conductor cables, compared with the difficulties bearing upon the study of multi-conductor outfits, and showed diagrams of potential gradients and gave formulæ for intensities and stresses The relations between diametrical ratios and dielectric constants and the effects of leakage conductance on charging current were considered. The insulation resistance of cable paper was given as about 10,000,000 megohms per cubic centimetre, and of rubber as 800,000,000 megohms per cubic centimetre. Grading of insulation was valuable in small wires and also in large conductors for high voltage service. The volume of insulation required for a given service was much less with graded cables, frequently from 25 to 35 per cent. of the quantity needed in ungraded cables. An approximate solution of potential distribution was possible for three-conductor cables, but this appeared to be out of the question in generator and transformer coils. The work of Dr. Russell and Mr. Watson in cable insulation testing, as discussed in the *Proceedings* of the Institution of Electrical Engineers, was reviewed, and graphic studies of charging currents and other phenomena were presented.

Economies of an Electric Signalling System.—Mr. F. P. Patenall, of the Baltimore Railway, in a recent report speaks in the highest terms of the efficiency and economy of the electric signal system compared with oil burning signals. On the Washington branch, between Baltimore and Washington, 69 electric lamps were lighted and extinguished 1,259,250 times, while on the Metropolitan branch, between Washington and Germantown, 38 electric lamps were lighted and extinguished 208,050 times. During this period there were but nine failures, four being caused by lightning and five by filaments burning out. When burning, the lamps consumed approximately half an ampere, and on the Washington branch, where 50 trains are running in each direction daily, each lamp burns 1 hour and 40 minutes each 24 hours, the lamps lighting upon the approach of trains both by day and night. The entire expense of maintaining the 107 signals during the year, including labour, was £2,157. It is interesting to note that 32·4 lb. of blue vitriol were used per signal per month. The current for lighting the lamps was obtained from the same source as that for operating the signalling motor—namely, six cells of a storage battery charged by 18 gravity cells for each pair of signals. At interlocking points, where frequently four signals are operated from the battery, seven storage cells are used, charged by 21 gravity cells. In conclusion, it is reported that the system not only operated more satisfactorily than the oil system, but with higher economy, the wages of five lamp men, equivalent to £45 a month, having been saved since the system was put in operation.

Street Lighting in the City of Westminster.—In connection with the street lighting contracts in Westminster we have received from the Westminster Electric Supply Corporation a copy of a proposal made by them in conjunction with their tender. It will be remembered that this Company already light the St. George's, Hanover-square, district by 962 open type arc lamps. This contract remains in operation until 1931. They offered, if they were given the street lighting in the rest of the district supplied by them, to change these lamps, free of charge, to flame lamps, thus increasing the total candle-power from 500,000 to 1,800,000 c.p. Metal filament lamps would also have been substituted where carbon lamps are now used. The electric supply company pointed out that the district is now lighted by 1,074 gas lamps giving approximately 90,000 c.p., while under the new specification the alternatives suggested would give 216,000, 264,000 and 682,200 c.p., or something intermediate between these values. In the first case the capital expenditure would be £3,600, and the maintenance £7,800 per annum; in the second and third the capital expenditure would be £4,000 and £13,220, and the maintenance £8,800 and £7,185 respectively. In the alternative proposal the capital expenditure would be nothing, and the maintenance £7,921 per annum. This alternative proposition would cost £75 per annum more than the price tendered, but by its acceptance it was pointed out the Council would obtain the same high standard lighting as laid down for the specified district in the adjoining area which is more than twice its size.

Terrestrial Magnetic Disturbances at Greenwich.—At a meeting of the Royal Society on April 28th, a Paper on "The Rotatory Character of some Terrestrial Magnetic Disturbances at Greenwich and on their Diurnal Distribution" was read by Mr. R. B. Sangster. The Paper commenced with an investigation of the changes in direction of the line of total magnetic force at Greenwich on October, 1903, $12^{d}\cdot 18^{h}\cdot$ to $23^{h}\cdot$ when a considerable magnetic disturbance was in evidence. Measurements of the published registers of all three force components were made at equivalent time intervals of about 5 minutes, whence was obtained a diagram showing the variation of the force component perpendicular to the line of total force. The diagram showed there was an almost wholly rotatory motion of the transverse disturbance vector, the trace consisting of six distinct convolutions varying greatly in size but consistent in anticlockwise progression. Several other disturbances during epoch 1900-07 were examined in detail, and it was shown that a right- or left-handed rotatory character in the motion of the disturbance vector was of fairly frequent occurrence, while change from left to right not uncommonly occurred about midnight. It was also found that the same direction of rotation often persisted for several hours, and tables of the diurnal distribution of right- and left-hand rotatory disturbance were furnished to show that those of right-hand character were entirely absent during the hours 4 p.m. to 9 p.m., while, meantime, the left-handed rotations were very prevalent and reached a notable maximum at 8 p.m. Other points in the diurnal distribution were noted, including the more decided effect resulting from a seasonal grouping of the seventy disturbed days dealt with.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. F. Fernie contributes an article on the subject of Electrolysis by Stray Currents and Its Effect upon Underground Cables.

We give an account of the discussion which followed the reading of Mr. S. G. Brown's Paper on "A New Telephone Relay" before the Institution of Electrical Engineers.

Dr. A. Ebeling recently read a Paper before the Electrotechnischer Verein, on the subject of "Long Interurban Telephone Lines on Pupin's System." We give a translation of this and a short account of the discussion which followed the reading of the Paper.

We give an account of the uses to which electricity is being applied on the Panama Canal.

Sir George S. Gibb is retiring from his close association with the management of the Underground Electric Railways of London in order to take up the position of chairman of the newly-appointed Road Board.

Heckmondwike Council have applied for sanction to a loan of £24,159 for their electricity department.

By the narrow vote of 18 to 17, Hampstead Council have referred back a proposal to substitute electricity for gas lighting throughout the borough, in order to afford the Gas Light & Coke Company an opportunity of fitting up a trial installation of about 20 inverted gas burners "for observation."

At the meeting of the Iron and Steel Institute last week, Mr. W. Borchers read a Paper on the Girod Furnace. We give an abstract of the Paper and the remarks of those speakers who took part in the discussion.

We also give an account of the discussion in connection with the Paper on "Electric Power in the Iron & Steel Industries," read by Mr. Selby Bigge at the same meeting.

An inquiry was held at Colchester last week into the application of the Council for permission to borrow £8,000 for extensions of the electricity undertaking.

Harrogate Council have decided to convert 500 lamps from gas to electricity.

Yarmouth Council are converting 192 gas lamps for electric lighting, and it is estimated that the annual saving will be £76. 6s. 8d. An inquiry was held on Tuesday into the application.

Grimsby Corporation have applied for permission to borrow £2,000 for street lighting.

Companies' Meetings, &c.—The report of the directors of the Calcutta Electric Supply Corpn. states that additional generating plant has been put down at the Ultadangha station of the Company and that negotiations are proceeding for the purchase of a site for a new high-tension generating station.

The directors' report of Callender's Cable & Construction Co. states that the value of the business done during 1909 showed a considerable reduction, compared with all recent years. Arrangements have been made for increasing the Company's business in foreign countries, and the engineering department at the Erith works has been extended.

INSTITUTIONS AND SOCIETIES.

Institution of Electrical Engineers.—On account of the death of His Majesty King Edward, the ordinary general meeting of this Institution, which was to have been held yesterday evening, did not take place.

The Royal Society.—In consequence of the death of His Majesty King Edward, Patron of the Society, no meeting of the Royal Society will be held until further notice.

Royal Institution.—In consequence of the lamented death of His Majesty King Edward (the Patron of the Royal Institution), and out of respect to his memory, the president has decided that the lectures and evening meetings will be discontinued until further notice.

Tramways and Light Railways Association.—Owing to the death of His Majesty King Edward, the Congress of this Association, which was to have been held at Dublin yesterday and to-day, has been postponed.

National Electrical Manufacturers' Association.—We are informed by the Secretary (Mr. F. B. O. Hawes) that some of the tickets for the meeting on Free Trade *versus* Protection, posted to members of the Institution of Electrical Engineers, appear to have gone astray. If any members desire to attend and find they have not received tickets, they are requested to communicate with Mr. Hawes.

Royal Meteorological Society.—In consequence of the death of His Majesty King Edward, the meeting of the Society which had been fixed for Wednesday, May 18th, has been postponed to Wednesday, May 25th.

Incorporated Municipal Electrical Association.—To meet the convenience of those who wish to travel to the meeting of this Association at Glasgow, arrangements have been made by our contemporary, "Electrical Industries," for special saloon carriages to be attached to the 2 p.m. train from Euston to Glasgow on June 13th. This train, which arrives at Glasgow (Central) at 10:20 p.m. will be found most convenient by visitors. It stops at Willesden, Rugby, Crewe, Preston and Carlisle—at all of which stations holders of the special tickets may join the saloon carriages. It is proposed to arrange a programme of entertainments in the train on the journey to Glasgow, and also, if possible, on the return journey on Friday, June 17th. Further, visitors may book hotel accommodation through our contemporary at the Grand Hotel, where a suite of rooms has been reserved. The special inclusive charge for guests so booked will be 5s. for room and breakfast. Applications for railway tickets and hotel accommodation should be sent at once to "Electrical Industries" (Special Train Department), 37-38, Strand, London, W.C.

Electrical Association of Victoria.—The annual meeting of this Association took place on March 17th. Mr. H. R. Harper, the retiring president, said there had been a large increase of members. A motion by Mr. W. J. Mountain that certificates should be issued to members of three or more years' standing was passed. A resolution was carried referring to the council the question of altering the name of the Association. Mr. A. Henrick Jackson, who was elected president, said they all looked forward to the amalgamation of the various electrical associations into one Australian Institute of Electrical Engineers. Mr. Percy Rosling and Mr. J. D. Gillan were elected vice-presidents. Mr. Rosling is also hon. treasurer, and Mr. E. H. W. Westwood is hon. secretary.

Mr. Jackson, in the course of his presidential address, said that in the early days, electrical men were more closely connected with mechanical engineering; now, with the perfection of electrical plant, the application of electrolytic methods to chemical processes, and the speculative researches as to the nature of the atom, the pendulum had swung into the domain of chemistry. He suggested as a subject calling for further attention, the question of the influence of minute quantities of foreign bodies on the capacity and life of secondary cells. Perhaps some of the University Research Fellowships might be dedicated to this end.

Arc Works Engineering Society.—The annual general meeting and conversazione of this Society was held in the Arc Works Club House, Writtle-road, on Friday, April 29th. The report of the committee for the past session showed that the Society was in a thoroughly satisfactory condition. Eighteen meetings have been held during the session at which Papers covering a wide range of subjects have been given by members and friends of the Society. The Society offers premiums for Papers read at its meetings by pupils and apprentices at the Works. The annual general meeting was followed immediately by a conversazione, which was presided over by Col. Crompton, and at which Lord Rayleigh was present. After a short musical programme a Paper on "Aeroplanes" was read by Mr. C. Crompton.

Glasgow Section of the Institution of Electrical Engineers.—At the meeting of this Section held on Tuesday last the following were selected as office bearers for the session 1910-11. *Past Chairmen*, Messrs. F. G. Bailey, W. W. Lackie, E. G. Tidd; *Chairman*, Mr. Sam Mavor; *Vice-Chairman*, Mr. J. A. Robertson; *Chairman of Students' Section*, Mr. H. A. Mavor; *Hon. Secretary and Treasurer*, Mr. J. E. Sayers; *Members of Committee*, Messrs. J. T. Bottomley, J. Ferguson, Magnus Maclean, J. C. Macmillan, Wm. M'Whirter, W. C. Martin, T. B. Murray, T. C. Parsons and Robert Robertson.

ARRANGEMENTS FOR THE WEEK.

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. B. Crompton, C.B.

The following orders have been issued for the current week:—

Tuesday, May 17th, "B" Company.—Company Drill, 7 to 9:30 p.m.

Wednesday, May 18th.—Gymnasium, 6 to 9:30 p.m.

Thursday, May 19th, "C" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7 to 8 p.m. Technical Drill, 8:45 to 9:45 p.m.

Friday, May 20th, "D" Company.—Recruits' Infantry Drill, 6 to 6:45 p.m. Company Drill, 7:15 to 8:30 p.m. Technical Drill, 8:45 to 9:45 p.m.

LONG INTERURBAN TELEPHONE LINES ON PUPIN'S SYSTEM.*

BY DR. A. EBELING.

Summary.—On the grounds of greater efficiency, of absolute reliability and of ultimate economy, long overhead trunk lines for telephone circuits should be replaced by underground cables. Leakance is a factor which cannot always be considered negligible in the calculation of the attenuation coefficient, and it is shown how the actual influence of any given leakance depends on the conductance. An accurate method, available for quite short lengths of core, of measuring the leakance at telephonic frequencies is described, and the figures for definite cores are given. Cable with "loadance" can be manufactured in which leakance is negligible.

The great havoc wrought by the snowstorms of November last in Germany, especially in the environs of Berlin, on the overhead telegraph and telephone wires, gave rise to numerous articles in the daily press in which the question was discussed as to whether it were not possible to obviate by the use of underground cables the disturbance to traffic caused thereby; but the conclusion generally reached was that though long telegraph circuits could be, and for some years past in Germany had been, placed underground, it was not possible to do the like for telephone circuits for efficient commercial traffic. The positive proof is here given that not only is it possible to lay long telephone lines underground which would be more efficient than overhead wires, but even ultimately more economical. This result has been arrived at by the Siemens & Halske A.G. as the result of actual experiments on the loading of cables with inductance on the Pupin system, which has been effected with the most striking results, and the benefits of which have caused its rapid introduction in most countries, especially for the industrial districts of the Lower Rhine and Westphalia, and for cable lines of several hundred kilometre lengths in North America. The special series of experiments here detailed were undertaken in order to clear up apparent differences between the actual observed values of the attenuation coefficient and those given by calculation from the electrical data of the circuit.

The attenuation coefficient determines the efficiency of any telephone circuit, and thus of a "pupinised" circuit, so termed because it differs from an ordinary circuit by the introduction of inductance coils at definite points according to the formulæ of Prof. Pupin. The general formula for the attenuation coefficient per kilometre is given by the expression

$$\beta = \sqrt{\tfrac{1}{2}[\sqrt{(S^2+p^2C^2)(R^2+p^2L^2)}+SR-p^2CL]} \quad . \quad (i.)$$

where $p=2\pi n$, n being the number of periods per second, R and L the effective resistance and inductance of the loop, and S and C the leakance and capacity taken wire to wire per kilometre. In circuits with high inductance, *e.g.*, pupinised conductors, this expression can be simplified and reduced to the form given by Prof. Breisig ("E.T.Z.," 1908, p. 588)

$$\beta = \frac{R}{2}\sqrt{\frac{C}{L}}+\frac{S}{2}\sqrt{\frac{L}{C}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (ii.)$$

L here includes the value per kilometre of the inductance added by the coils. The leakance S is the reciprocal of the apparent insulation resistance and has been generally assumed as negligible seeing that the insulation with direct current, especially in the case of paper cables, is of the order of thousands of megohms; hence if S=0, the two expressions above become respectively

$$\sqrt{\tfrac{1}{2}pC(\sqrt{R^2+p^2L^2}-pL)} \quad . \quad . \quad . \quad . \quad (iii.)$$

and

$$\tfrac{1}{2}R\sqrt{\frac{C}{L}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (iv.)$$

Béla Gáti was the first to announce the fact that ("Measurement of Electrical Resistance," by Barretter, "E.L. and M.B.," 1908, sec. 13) in ordinary paper-insulated telephone cables a very much lower value of insulation obtained for alternating currents at frequencies comprised within the limits of human speech, and in the cables he tested he found that at 2,000 ~ the insulation was about 0·1 megohm or only about one ten-thousandth of the value given by the usual method of direct-current measurement. These measurements were obtained by the alteration in the resistance of a very thin wire, heated by the alternating currents at the frequency in question, observed first on a short piece of the cable, and then on a condenser of the same electrostatic capacity, with a resistance in parallel, adjusted until the current was the same in the two cases. Prof. Breisig has also (*loc. cit.*) directed attention to the effect of this leakance value on the attenuation coefficient in pupinised cables.

While Béla Gáti found a leakance, as above stated, of about 10 micromhos for paper cables, Prof. Breisig by calculation from tests made on a submarine cable, found a leakance of 2·3 to 3·8 micromhos per kilometre. The construction of this cable differed, however, from the normal, in that the copper stranded conductors were close wound with layers of fine iron wire. Attention may be at once drawn to the fact that in the comparatively short pupinised cables laid by the Telegraph Administration, conductors of light section have been employed, and the attenuation coefficient is fairly high, and that in such cases leakance plays but a very small part; but as soon as the problem is entertained of laying long cable lines, heavier conductors will have to be adopted, so as to reduce the attenuation coefficient and that then leakance may play a prominent part.

The following Table I. has been calculated on certain assumed data to exhibit this influence; the values per kilometre being L=0·1 henry, C=0·04 mfd., while the leakance has been taken at 10 and 3 micromhos, as above found in definite instances and also at 1 and 0·5. The resistance of the conductor, including that of the loading coils, is taken at 70 and 10 ohms for the two sets corresponding to conductors of 0·8 and 2 mm. diameter respectively.

Table I.

R, ohms.	L, henry	C, mfd.	S, micromhos.	βR.	βS.	β.	Δ%
70	0·1	0·04	10·0	0·0221	0·0079	0·0300	36
70	0·1	0·04	3·0	0·0221	0·0024	0·0245	11
70	0·1	0·04	1·0	0·0221	0·0008	0·0229	4
70	0·1	0·04	0·5	0·0221	0·0004	0·0225	2
10	0·1	0·04	10·0	0·0032	0·0079	0·0111	247
10	0·1	0·04	3·0	..	0·0024	0·0056	75
10	0·1	0·04	1·0	..	0·0008	0·0040	25
10	0·1	0·04	0·5	..	0·0004	0·0036	12

The column headed βR gives the value calculated from the first member of formula (ii.) when leakance would be neglected, βS that calculated from the second member of that formula, the next column contains the sum of these two, and therefore the true value, while the last gives the percentage difference due to βS. With the resistance of 70 ohms it is only the 10 micromhos leakance that introduces any considerable alteration, while on the other hand, with the resistance of 10 ohms, it is only the leakance of 0·5 that is of negligible import. The values here assumed were chosen intentionally, so as to exhibit the subject in a convincing manner, but with the lower resistance the influence of leakance would be lessened by reducing the inductance, as shown by Lüschen ("On the Effective Leakance of Telephone Cables, and the Effective Time Constant of Pupin Coils," "E.T.Z.," 1908, p. 1105), in special cases. By the choice of suitable coils some decrease in the βS term can be secured without great increase in βR. Prof. Breisig's figure of about 3 micromhos agreed satisfactorily with the values deduced by other measurements from the attenuation coefficient on some lengths of cable, but this was an exceptionally high figure, and we believe that for paper cables in general their leakance may be taken as very small, even if not completely neglected. There remains the further hypothesis that even if the leakance be negligible, and differences between the calculated and observed values of the attenuation still exist, such may be ascribed to some unknown losses in the coils themselves; so that investigation of their leakance was also necessary. It was clearly obligatory to find some reliable method of directly measuring the leakance itself, even when its amount was very small.

*A Paper read before the Electrotechnisches Verein. Translation communicated by the author. "E.T.Z.," 1910, p. 420.

The solution of this problem was found by Dr. Adolph Franke and is based on the method and form of apparatus described in detail by him in his thesis for the Doctor's degree, published in 1891. (A. Franke, "The Propagation of Electricity in Telephone Conductors and Apparatus," "E.T.Z.," 1891, p. 447.) This Paper contains a full description of a special form of high-frequency alternate-current machine, which he, being at that time in the service of the Government Telegraphs, had had constructed at their instance and with which he conducted a full series of measurements on the electrical constants of telephone lines and apparatus. The same machine and methods have also been employed by Dr. Breisig in his valuable researches.

In the course of his general treatment of the subject, Dr. Franke states the following simple equation as applicable to circuits if of no great length,

$$I/V = Sx + i2\pi nCx. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (v.)$$

where I and V are the current and voltage at the beginning of a line insulated at the far end, S the leakance, C the capacity (both per unit length), n the frequency and x the length of the circuit.

Introduce into the circuit of the alternating current in series with C_2 the short length of twin insulated conductor with the other ends free, an adjustable condenser C_1, which has no measurable leakance, and adjust the capacity until the voltage across its terminals is the same as across the cable. Then at the terminals of the condenser

$$I/V_1 = i2\pi nC_1. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (vi.)$$

and of the cable

$$I/V_2 = S + i2\pi nC_2. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (vii.)$$

where S and C_2 are the values for the length under test, the current I being the same in both.

Hence $$\frac{V_1}{V_2} = \frac{S + i2\pi nC_2}{i2\pi nC_1} = \frac{S}{i2\pi nC_1} + \frac{C_2}{C_1};$$

but with voltage of true sine curves,

$$V_1 = Ke^{i2\pi nt},$$

and $$V_2 = Ke^{(i2\pi nt + \alpha)};$$

Hence $$\frac{V_1}{V_2} = e^{-\alpha} = \cos\alpha - i\sin\alpha = \frac{C_2}{C_1} + \frac{S}{i2\pi nC_1},$$

and therefore $\cos\alpha = 1 = \frac{C_2}{C_1}$ and $\sin\alpha = \alpha = \frac{S}{2\pi nC_1}$,

where α, the phase difference between the voltages at the condenser and cable terminals, is a very small angle, and therefore

$$S = \alpha 2\pi nC_1. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (viii.)$$

The angle α is usually of the order of a few minutes of arc, and as the original machine did not allow of measuring such a small angle within the requisite limits of accuracy, a special one was constructed with the necessary modifications so as to allow of a finer reading being taken, the details being worked out under the assiduous attention of Mr. A. Becker. The figure for the leakance on long lines deduced by the indirect method of measurements conducted by the Testing Department of the Telegraph Administration were not rendered any more accurate by the use of this modified machine.

From the value of S for the length of cable tested, the value per kilometre is given by simple proportion, and the angle α is a constant for any short length of the same type of cable. Thus, with one type of cable the angle α was measured at 12′ to 13′ when the length of cable was increased from 75 to 150 metres, and in all our measurements these are approximately the limits of the lengths that were tested.

As the angle α was also found to be constant for different frequencies, the actual value depending on the nature of the core tested, it appears that the leakance is directly proportional to the frequency. The accuracy of this method was fully confirmed by testing a condenser in parallel with a known constant resistance, as S and C being both constant quantities, α would vary inversely as the frequency. Table II. gives the results of the measured and calculated values for a condenser

Table II.

of 0·00605 mfd. in parallel with an alcohol resistance of 6·6 megohms.

The agreement between these figures is satisfactory as the limit of error in the measurement of the angle was about 2′.

In the case of the cable which was used for the most important experiments, and which was specially adapted for the Pupin system of loading, the leakance per kilometre at 900 ∿ was 0·45 micromho, the variation in separate conductors being less than 4 per cent. In two gutta-percha-insulated cores which happened to be available, but not of usual submarine cable dimensions, immersed in salt water, the leakance per kilometre at 900 ∿ was 9·3 and 10·6 micromhos respectively, which agrees with the value found by Prof. Breisig on a gutta-percha cable having cores with continuous inductance, where the increase of leakance with periodicity is noticeable, but in whose figures for paper cable no such alteration appears.

Our tests, however, of paper cores with conductors of 1·5 mm. diameter show a maximum leakance per kilometre of 0·74 micromho at 900 ∿. Numerous tests were made on various types of cables and conductors, which give promise of great interest as to the nature of leakance, but the account of these must be reserved for a future occasion. This same method can also be applied to the testing of the inductance coils themselves, as they may be treated as conductors with evenly distributed capacity. One type of coil, inductance 0·2 henry, gave a leakance of between 0·036 and 0·04 micromho while in another type of the same inductance 0·21 to 0·28 micromho was found; both of which types have been used in the loading of cables recently laid, and may be taken as of normal manufacture, so that a very small leakance is evidently obtainable in such coils. Being now in possession of all the necessary data for the leakance of cable and coils, it was possible to check the agreement between theory and practice for Pupin's formula by actual measurement, introducing the correction, of course, of his sine rule which gives the relation between the values obtained on circuits containing continuous and spaced inductance. For this purpose it was necessary that the measurements of the attenuation coefficient should be accurately effected, and though the method used by the Experiment Department of the German Telegraphs was available, and which we need not now describe, it labours under the disadvantage of requiring long and tedious calculations from the figures given by the readings, and for our ends a method, if equally reliable, was desirable, which would allow a speedy calculation, because, as may be imagined, a very long series of tests had to be made, before reaching the simple results ultimately attained.

Had it not been possible to measure the leakance itself directly, then any difference between calculation and observation could be ascribed to some variation in such leakance, and in spite of many special experiments, the conclusion had been arrived at, that an accurate value of the leakance was not obtainable by the indirect method previously stated, as so many different factors entered simultaneously into the question, now cleared up by the independent measurement of the leakance. A simple method of determining the attenuation coefficient is afforded by the measurement of the current at the near and far ends of a circuit, provided it be of sufficient length. Most of the readings were taken by oscillographs which recorded simultaneously the curves of the two currents, from the amplitude of which the intensities could be determined. By the equation $I/I_b = 2e^{-\beta l}$, where these are the currents at the beginning and end of the line of length l, the value of β is readily calculated. The length of line was usually about 100 km., and the results given by this method and that of the Government Department were in thorough

Digitized by Google

concordance, if the line was of the sufficient length as above stated. Tests were also made with the Franke instrument, by measuring the voltage at the terminals of inductionless resistances interposed at the two ends of the line and thereby determining the two currents; this method had the disadvantage of introducing high resistances into the circuit as compared with the extremely small resistance of the oscillograph; but both methods gave equally concordant and sufficiently reliable results. The main series of tests were made on a 10-pair paper-insulated cable with 0·8 mm. conductors, which was available in separate equal lengths of 1,300 metres, so that an even distribution of the inductance coils, *i.e.*, at 1,300 metres apart, was obtained, and the frequency generally was 900, which may be taken as representing the mean tone of the human voice, but measurements were made at other periodicities also, and in Table III., are contained the values obtained at 500, 900 and 1,200 ∿, at which observations could be made with the greatest accuracy, and which cover all practical requirements. This table gives the frequency and the mean values of the effective resistance, inductance, capacity, and leakance all measured for a length of 1 km. of the twin core, taking into account the separate values for cable and coils; the attenuation coefficient βR, if only the first member of formula (ii.) is used, and which may be considered the ideal value of β; then βP, which includes the increase due to Pupin's sine rule, and then βQ, taking into account all the factors, including leakance, and which is the correct value given by calculation; the last column βM gives the values found by actual measurement. The agreement between these last two columns is extremely close.

The figures under A and B are for cables equipped with coils of similar form but of slightly different construction, the leakance of which was very small and, in fact, equal to that of the first type of coil previously mentioned, *i.e.*, about 0·04 micromho. Under B are given the mean values of observations made on several days both by oscillograph and Franke's machine, and under A the results of one set of observations alone, and in this case also the difference between calculation and measurement is extremely slight. The difference between βQ and βP reveals the effect of leakance and varies for the periodicities given between 2 per cent. and 4 per cent.; but, as already stated, leakance would play a much more conspicuous part in a cable with heavier conductors. On referring back to Table I., it is seen that the leakance here measured corresponds to about the value of 0·5 micromho, and is thus of little moment; and even with the leakance of 1 micromho, the increase in attenuation could, as already mentioned, be counteracted to some extent by a reduction of the inductance. This treatment of the question, where high leakance obtains, has been considered by Lüschen (*loc. cit.*) and by Devaux-Charbonnel ("Etudes sur les Lignes Télégraphiques," "La Lumiére Electrique," 1909, 327), but with paper cables this difficulty does not enter, as it is possible in their case to secure very small leakance. Other measurements were made on a cable actually in work, with conductors of 0·9 mm., the leakance of which had not been measured before the cable was laid, and Table IV., column 2, contains the values of β, given by calculation from the electrical data, omitting both Pupin's sine rule correction and the leakance; column 3 gives the figures corrected for the former omission, and column 4 the actual measured value, and, by application of formula (ii.), it is easy to determine the leakance, which is, of course, the sum of that of cable and coils, and these are set out in the other columns, 4 giving the value thus calculated, 5 the same under the assumption that the leakance is proportional to the periodicity, and taking 0·59 at 900 ∿ as the basis. The coils were of similar construction to type 2, above mentioned, with a leakance of 0·25 micromho at 900 ∿, and the value per kilometre is given in column 7, while the difference, column 8, gives the leakance of the cable alone, which is shown to be very small and at the same time to be in concord with the actual values, obtained on the experimental cable, given in Table III.; but this is not remarkable, as these cables were of the same special construction, though these extremely close values are no doubt partly fortuitous. The results of our experimental research may therefore be stated shortly as follows:—

1. Cable loaded on Pupin's system gives results absolutely in accordance with theory.

2. Cables manufactured by the Siemens & Halske, A.G. specially for the application of this system, have such low values of leakance that its influence on the attenuation coefficient is negligible.

3. A short length of cable is sufficient for the accurate measurement of the actual leakance.

4. A negligible leakance in the inductance coils can also be secured.

We are, therefore, in possession of data, the gaining of which, however, was no mean labour, which furnish us with the means of giving a definite decision as to the length of cable which it is possible at the present time to work loaded on the Pupin system.

Adopting the electrical values which we have now at hand for calculating the attenuation coefficient, we are in a position to state that with coils of the best form, and cable properly constructed, efficient working can be secured on trunk lines of 1,000 km. in length without a greater diameter of the conductors than 3 mm. All important trunk lines in Germany would be shorter than this.

It must be remembered that this conclusion is due to the fact that circuits composed of cable alone can be worked with a less volume of sound than overhead circuits, because the latter, liable as they are to great changes in insulation, never afford the efficiency theoretically allowed, and are also much more subject to external disturbances, so that heavier conductors must be employed than would be otherwise necessary; while in a cable this extra reserve of power is not required, because the efficiency once established is always the same. Special experiments conducted by the Siemens & Halske A.G. have shown that for long telephone lines a value of βl between 3·5 and 4 is not too great. This product of attenuation coefficient and length, first introduced by Prof. Breisig as the efficiency factor, and termed by him the "attenuation exponent," gives a clear picture of the value of any circuit in a simple form. An increase in the size of conductor will in general secure with an increase of the length the same value of βl. It was a simple matter, therefore, to arrange different values of βl in the testing room where 300 km. of 0·8 conductor cable was available; on which, loaded with inductance coils, a value of βl up to about 6·5 was attained, at which figure the volume of sound was extremely low but the articulation still clear.

Experiments were also instituted, with the co-operation of the telegraph authorities, on lines under actual traffic conditions, which showed that the attenuation was but slightly affected by the interconnections at the different exchanges.

Though we have shown that, on technical grounds, no difficulty can be urged against the laying of long telephone cables, the question has still to be considered in its economic aspect, and a complete answer can be furnished only by the Telegraph Administration who have ready at their disposal all the requisite data. We can, however, arrive at some

Digitized by Google

approximate idea, at any rate applying to long trunk cables where the number of circuits to be provided is not too restricted, *i.e.*, for interconnection of important towns between which considerable business is carried on. As such towns will, however, be served by a certain number of overhead lines already in existence, it will not be possible to replace them by cables with an actual saving of expense, so that we can limit the question merely to the case either of the number of circuits being so great that difficulty is experienced in adding any more, or to that of the advantages accruing from the use of underground cables as being of sufficient weight to warrant this extra first cost, and of this extra cost being recouped in future years.

The advantages afforded by the cable circuits may be stated as follows :—

1. The efficiency of communication once secured is always the same, barring actual faults, which, of course, occur very seldom.
2. Cross talk is effectively eliminated.
3. No interruption is occasioned due to disturbance from external causes.
4. No anxiety is felt as to the cost of repairs due to snow-storms, &c., nor as to interruption of traffic caused thereby.
5. The maintenance of the cables is a much smaller item than that of overhead lines.
6. On laying the cables, a certain number of spare wires can easily be provided, which will allow for the easy development of the trunk communications.
7. The reliability and rapidity of communication gains the confidence of the public, and the use of the telephone thereby extended warrants the introduction of such reserve circuits.
8. By the sale of the bronze overhead wires, which at the present time command a high price, the expense can be considerably reduced.

Even putting on one side the reliability and excellence of communication, which take first rank in the appreciation of the public, and also the introduction of spare wires, which would entail some little extra expense, we still have the actual items of reduced maintenance which in the course of the life of the cable would be considerable. A definite figure on this point is available from the Paper communicated by Major O'Meara, engineer-in-chief of the British Postal Telegraphs, to the Congress at Budapest (K. Strecker, International Congress of Telegraph Engineers at Budapest, 1908, "E.T.Z.," 1909, p. 127), according to which the maintenance of an overhead wire amounts to 2·9 marks or, say, 3 marks per annum per kilometre more than for a wire in an underground cable; while as regards reserve wires we should be able, by adopting, as has been the practice for some time in England, the Dieselhorst-Martin type of cable, to limit considerably the actual number of reserve wires, since independently in addition to the single pairs, 50 per cent. of reserve is provided owing to its special construction, as in this type the well-known combination of two metallic circuits to form a third metallic circuit is available, the possibility of which in overhead circuits is negatived by the variable and low state of their insulation, while in ordinary underground cables this combination is, owing to cross talk, rendered impossible.

The special pupinisation of these extra circuits can also be effected only as they come into use, *i.e.*, as the circuits become fully occupied.

That the cost of the telephone cables will not be inordinately high the following instance will show. Assume a line 500 km. long (about the mean length of important trunks in Germany), and that the route is already supplied by 14 circuits of 4 mm. overhead bronze wires, a cable of 28 pairs will be adopted, as it is a certainty that the number of circuits would soon have to be increased. The cost of such a cable, including the laying and equipping with Pupin coils, will be about 10,000 marks per kilometre, or, say, a total of 5 million marks. By the sale of the bronze wires about 2 million marks could be recouped, less the cost of removal, which shows the comparatively high value of the break up cost of this wire; and thus a total first cost of about 3 million marks would be entailed. The annual saving of cost in the maintenance of this cable would, according to the figure given above, amount to 84,000 marks, as compared with an equal number of overhead circuits, which represents a considerable interest on the capital; but if the gain in increase of receipts due to the reliability, security and rapid development of traffic be taken into account, and it be remembered that cables as now constructed are very long lived, and the sinking fund for their renewal correspondingly low, the conclusion may safely be drawn that the laying of important telephone cables is to be advocated on economical grounds.

The length of important trunks in Germany would reach a total of about 4,000 km., which, for 28 pair cable, would represent a total outlay of 50 million marks, reducible to 30 million marks by the sale of the existing bronze wires. But if the decision be taken to place all the important conductors underground, the telegraph lines would also come into this category, and with this in view, there would be no hesitation at the present day in inserting them into the same cables with the telephone wires, without any fear of inter-disturbance; this is proved by the long lengths of such combination cables now laid in England; though naturally, if the number of conductors of each class is sufficient, separate cables could be laid.

The question has been confined solely to cables loaded on the Pupin system, *i.e.*, with inductance added at distributed points, as cables with continuous self-induction are practically ruled out, owing to the lengths required, as well as on economical grounds.

As to the efficiency of such cables, a clearer view is also now presentable as a consequence of the results above given for their leakance; we hope to return to this subject in the future.

At any rate, we think we have proved that no hindrance now exists to the placing in cables of all important trunk telephone lines in Germany, and thus freeing our telephonic communications from all uncertainty and disturbance, which in the towns themselves has been already secured by the networks of underground cables which are everywhere replacing the overhead wires.

DISCUSSION.

Prof. BREISIG was the only one who made any remarks at the reading of the above Paper, and these may be summarised as follows :—

The author states that for the 1,000 km. lines he adopts an attenuation length of 3·5 to 4. Our trunk lines in Germany have only 1·5 to 3. With the former figure communication is carried on as if, so to say, the subscribers were in adjoining rooms, and is afforded by such lines as Berlin–Cologne or Berlin–Hamburg, and the latter obtains for longer lines, such as to Copenhagen, in which the volume of sound is very different from that of the former, and careful attention is required. The experiments made at "Wernerwerk" certainly gave good communication with $\beta l = 3{\cdot}5$, and even fair with $\beta l = 4$, but this was between skilled employés, and would not be sufficient for the general public, and if attenuation lengths of 3·5 to 4 were adopted instead of the present values of 2 to 3 as the limit, protest on protest would be received from the telephone subscribers. The mode of representing the attenuation coefficient given by Campbell in his Paper on "Loaded Telephone Circuits," communicated to the "Phil. Mag." in 1903, a Paper which, by the way, deserves to be more widely known than it appears to be, gives the clearest view as to the effect of leakance, and is $\beta = \frac{R}{2}\sqrt{\frac{K}{L}}\left(1 + \frac{S}{K}\cdot\frac{L}{R}\right)$ (misprinted in the "E.T.Z."). The proper division of cost between that of coils and core separately, in order to procure a cable of given attenuation length at the lowest cost, is a question still remaining for consideration. In the test with the oscillograph, the reflected current wave, which, in the simple formula used for determining βl by the ratio of the sent and received currents, is neglected, was still about 2 per cent. of the direct wave, and therefore of the same order of magnitude as the differences due to leakance shown in Table III., so that it is hardly conceivable that the results of observation can be taken as confirming calculation, especially as the received current also was only a small percentage of that sent. On the question of the inferiority of overhead lines, special experiments have been made by comparing long trunk lines with standard artificial cable, and the results showed that an addition of 0·5 to the attenuation length was sufficient to allow for the disturbance arising from external causes. For the line Berlin–Paris, 1,100 km. in length, the attenuation length is 2·2, which contains ample allowance for leakance over the calculated value. No doubt, however, can now exist as to the benefits to be derived from the pupinisation of U.G. cables.

Dr. EBELING, in reply, agreed that the oscillograph tests showed merely that no discrepancy could now be detected between observed and calculated results, and stated that further experiments would be put in hand with cables containing heavier conductors, for which the more accurate methods of testing, as used by the telegraph department, would be employed.

COMMUTATION PHENOMENA AND MAGNETIC OSCILLATIONS OCCURRING IN DIRECT-CURRENT MACHINES.*

BY G. W. WORRALL, M.SC.

Summary.—In the first part of this Paper the author, after discussing the theory of commutation, describes a research on the influence of contact resistance, speed, commutating E.M.F. and width of commutating pole on commutation, the phenomena being studied by means of the magnetic oscillations recorded by search coils on the pole shoes. The cause of the difference in behaviour of the positive and negative brushes is also investigated. The latter portion of the Paper is devoted to an examination of the magnetic oscillations occurring in various parts of the machine.

The experiments described in this Paper were undertaken as an extension to direct-current machinery of the investigations upon alternators which the author had previously been engaged upon.†

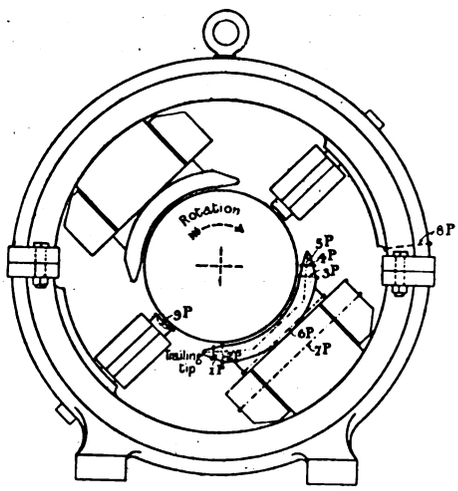

FIG. 1.—DIAGRAM OF MACHINE AND POSITION OF COILS ON POLES.

The magnetic oscillations were observed by means of E.M.F.s induced in search coils placed on the machine parts in such positions as to link the oscillating flux. The E.M.F. waves were photographically recorded by means of a Duddell high-frequency oscillograph and revolving drum camera. The machine employed in the investigation was a two-pole generator with adjustable commutating poles; the brushes were of carbon and of a width equal to one commutator segment plus insulation.

The principal details and conditions of running of the machine, of which a diagram is shown in Fig. 1, are given in the Paper. Search coils were placed on the pole system and armature as shown in Figs. 1 and 2. The analysis of the oscillations recorded was only

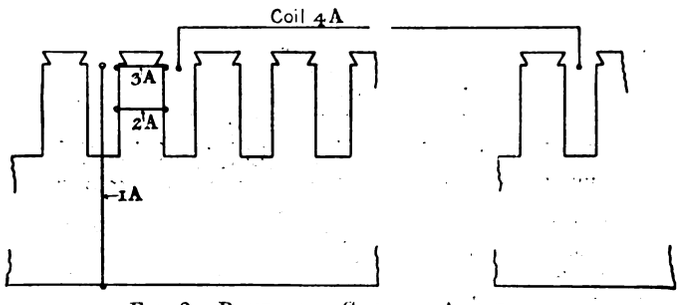

FIG. 2.—POSITION OF COILS ON ARMATURE.

possible by the accurate knowledge of the position of the armature corresponding to a point on the oscillograph record. This was obtained by means of a contact maker placed on the shaft of the machine and connected up to the oscillograph in the way devised by the author for the previous researches. During the instant of contact the oscillograph was shunted by a small accumulator, thereby producing a momentary current and hence an isolated peak in the record which was being taken. This peak corresponded to a predetermined position of the armature.

The contact maker employed was described by Arnold in "Die Gleichstrommaschine," Vol. I., and as no description appears to have been published in England a translation is, with the kind permission of Prof. Arnold, given below: "The construction of the contact maker is shown in Fig. 3. The contact is not of the rubbing type but of the pressure type, and the duration of contact is so short that the apparatus works well even with alternating current of high frequency. The apparatus consists of a contact disc, S, rigidly coupled to the machine shaft, a graduated disc, T, and a movable ebonite piece, G. On G are mounted, insulated from each other, the two contact springs f_1 and f_3 and the opposing springs f_2 and f_4. On S is mounted a raised steel piece n_1. G is rotated to any desired position relative to n_1 and clamped by the screw s. The finger z serves to read the position of G. The current circuit through the conductors a and b is closed once in each revolution when n_1 comes under f_1; f_1 is thereby raised until it comes into contact with the contact surface k_1 of the spring f_3. But the contact continues only for an instant, for in the next instant the springs f_1 and f_3 are together raised and break the contact at K_2 on which f_3 rests. In order that contact shall not be made again after n_1 has passed, there is a second piece, n_2, displaced axially and radially to n_1 which raises f_1 and holds it up until f_1 returns to its original position. The contact maker was devised by G. Schade, mechanic of the Electrotechnical Institute at Karlsruhe. The Physical-mechanical Institute of Dr. Th. Edelmann, at Munich, has undertaken its manufacture." The contact maker was found to be absolutely certain and accurate; the duration of contact was, at the normal speed of the machine, considerably less than $\frac{1}{10000}$ second.

The magnetic oscillations occurring are due to two main causes: (1) Movement of the armature teeth in the magnetic field; (2) commutation of the armature current in the short-circuited coil. The first class of oscillation was fully dealt with in the previous Papers on alternators, and the results then obtained apply equally to direct-current machines. The oscillations of the second class were found to be far more important, and in most parts of the machine greater

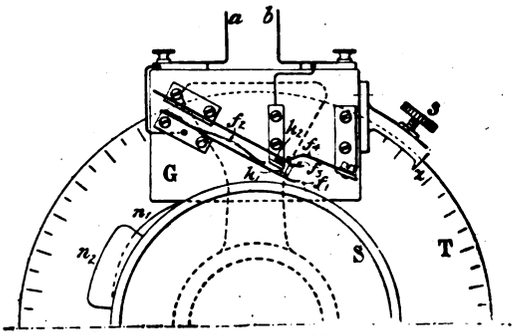

FIG. 3.—CONTACT MAKER.

in magnitude than those of the first class. These oscillations were due to the change of current in the short-circuited coils, and since there were two such coils there were two sets of oscillations, which were displaced relatively to each other 180 deg. owing to the number of commutator segments being odd (45). Although the currents in the two coils changed in relatively opposite directions, the position of one coil was the reverse of that of the other and hence the magnetic oscillations produced were in the same direction. Thus the number of oscillations occurring in a revolution of the machine was twice that of the commutator segments. The coil at the instant of short-circuit was opposite to a pole-piece and linked the main flux, hence the magnetic oscillation caused a pulsation in the main magnetid circuit which could be readily observed by means of the search coil 5 P wrapped round the pole-shoe. Since the flux at each instant is proportional to the current in the short-circuited coil, the E.M.F. induced in a search coil linking the flux forms a picture of the commutation taking place.

The usual method of commutation research is to measure the short-circuit current directly by means of a resistance inserted in an armature coil, but this method only gives results for two adjacent segments and the coil between them, and gives no indication of the nature of the commutation taking place at other points of the commutator. Such results are liable to be very misleading, due to the brush not making uniform contact. The method here adopted is free from all such objections, and by its means many interesting and important phenomena have been brought to light.

COMMUTATION PHENOMENA.

Theory of Commutation.—The theory of commutation has been the subject of very considerable discussion in recent years. On the one side it is stated that commutation should take place in a neutral field, while on the other it is stated that commutation should take

* Abstract of a Paper read before the Birmingham local section of the Institution of Electrical Engineers.

†*Journal*, I.E.E., Vols. XXXVII., XXXIX., XL.

Digitized by Google

place in a commutating field. The author shows that both lines of reasoning lead to the same result (that the direction of the resultant perpendicular velocity of the coil side coincides with the direction of action of the resultant field), and the apparent diversity of opinion is merely due to different methods of expression. These conditions for good commutation cannot hold in practice during the whole of the commutation period, but only during the final instant. It is, however, generally possible to obtain satisfactory commutation without compensating or rendering non-existent the self-induction E.M.F. of the coil. This may be effected by a proper choice and disposition of the contact resistance of the brush.

The author obtains an equation for the necessary variation of the contact surface over the rear segment, and Fig. 4 shows the shape of the brush surface to comply with the equation. The shape of brush obtained in this way, although not in itself practicable, points the way to the proper disposition of the resistance over the contact surface to obtain approximately straight-line commutation. The resistance of the contact surface over the rear segment must be very low compared with that over the forward segment, and this relation must hold not merely at the end of the period but quite early in the period. This disposition of the resistance may be approximated to by cutting away a portion of the surface of an ordinary brush as shown in Fig. 5. In this way the resistance to the forward segment is made high before, say, one-half of the short-circuit period has expired. The direct effect of such a disposition of the contact resistance is that the P.D. forcing the current to change is made high during the early portion of the short-circuit period, and hence the commutation is accelerated at the beginning instead of at the end of the period. This prevents a rush of current at the final instant, and renders the current change much smoother. The magnitude and disposition of the contact resistance and the self-induction of the coil determine what may be called the natural period of commutation, while the mechanical design and speed of the machine determine the available period.

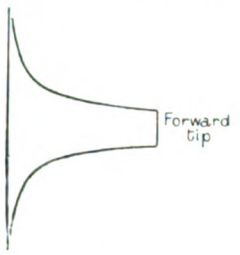

Fig. 4.

The natural period may be defined as the time required for the current to commutate under the conditions existing in the circuit of the coil, while the available period is the duration of the short-circuit.

Although theoretically the current would always occupy the whole of

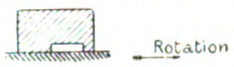

Fig. 5.

the available period in commutating, practically the current would reach a value closely approximating to its final value in a certain definite time which may be less than the available period. The available period in a given machine is proportional to the speed, but the natural period was found to be but slightly influenced thereby. The relation which the one period bears to the other, and the actual magnitude of the natural period, determine the efficiency of commutation. By efficiency is meant not merely whether the commutation is sparkless or not, but whether the commutation takes place with the maximum rate of change of current at its lowest possible value. The simplest way of varying this relationship is by varying the speed of the machine. Hence there is a certain critical speed below which the machine is sparkless and above which sparking takes place. When the conditions are such that the natural period cannot be adjusted sufficiently to obtain efficient commutation, an external or commutating E.M.F. must be introduced into the circuit. If the commutating E.M.F. be provided by means of commutating poles, the presence of the latter considerably increases the self-induction of the coil and the flux due to armature reaction in the commutating zone. The latter must be opposed by an equal flux from the commutating poles before any commutating E.M.F. is generated in the short-circuited coils.

So far nothing has been said with regard to the polarity of the brush, and indeed it is usual not only in theory but in actual experimental work to pay no regard to this point. But it is well known that the contact resistance of the positive brush is different from that of the negative brush. In fact, it is quite possible, as indeed was found in this research, for an alteration of the conditions which improves the commutation under the negative brush seriously to deteriorate the commutation under the positive brush. Thus, for example, the slit cut in the brush, as in Fig. 5, may improve the commutation under the negative brush, but may render the commutation under the positive brush much worse.

The above theoretical considerations may be summarised as follows: (1) In order to neutralise or render non-existent the self-induction E.M.F. of a coil at any instant the relative movement of the field and coil side must take place along the line of action of the resultant field at that instant. (2) Efficient commutation may be effected by a suitable adjustment of the natural period of the coil, and this may be done by properly disposing the contact resistance over the brush surface. (3) When the contact resistance is properly disposed the resistance to the forward segment is relatively high at an early stage of the commutation period. (4) Sparking at the forward tip of the brush is due to the available period being shorter than the natural period. (5) For every machine there is a critical speed at which the available and natural periods are just equal to each other, and below which the machine runs sparklessly. (6) A reduction of the natural period accelerates commutation during the early part of the short-circuit period, and increases the efficiency of commutation by lowering the maximum rate of change of the current, thereby causing a better distribution of current over the contact surface accompanied by a reduction of temperature. (7) The acceleration may be effected by a commutating E.M.F. If the natural period exceed the available period and the commutating E.M.F. be too small, sparking takes place at the forward tip of the brush, and if the commutating E.M.F. be gradually increased the commutation is shifted backwards until sparking takes place at the rear tip of the brush. (8) The natural period of the coil when short-circuited by the positive brush is not necessarily the same as when short-circuited by the negative brush.

Brush-holder.—In the early stages of the research it was found that the commutation was exceedingly irregular. It was thought that these irregularities were mainly due to mechanical defects of the brush-holder, and as the work proceeded this view was fully confirmed. Several types of brush-holder were tried, including the finger and reaction types, but with all these the contact surface was by no means constant. This was found to be due to a variable coefficient

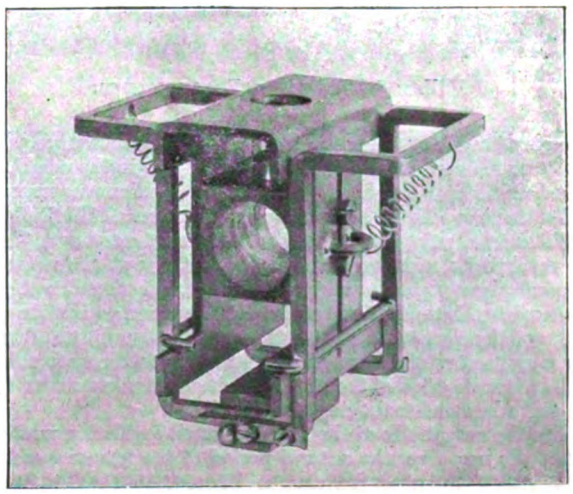

Fig. 6.—New Type of Brush-holder.

of friction between the carbon and the commutator surface, and to slight differences in the commutator surface. The incapability of the brush to adjust itself automatically to such varying conditions caused the commutation to be very uncertain in its nature. The author had the opportunity of examining some of the most modern brush-holders in actual use, and found that in all these the same difficulties existed, that the contact surface was not certain, and that the contact pressure was not uniformly distributed. A very common evidence of this is that the surface, when newly rubbed up with emery paper and allowed to polish by running the machine, polishes up first at the rear tip owing to the tipping effect of the friction.

A new brush-holder (*see* Figs. 6 and 7) was designed and constructed entirely free from these objections, and was used in all the experiments described in this Paper. The holder consists of a carrier, A, mounted on the brush bar, and clamped thereon by the screw B. A double plate, C, is mounted and capable of sliding on the carrier A, and is guided in its motion by a stud working in the slot D, and can be clamped in any position by the screw E. Two metal frames, F_1 and F_2, are held against this plate by the springs G_1 and G_2, respectively, in the positions shown. Their lower ends are formed into half-bearings, which press on to the axis H, upon which the carbon is mounted. The carbon is free to rotate upon the axis H, and is prevented from moving with the commutator by the tangential force exerted by one of the frames, F; one frame corresponds to each direction of rotation, and is inoperative in this respect when the rotation is reversed. Either end of the brush axis is free to lift independently of the other end. Hence the brush is free to adjust its position to any change in the commutator surface radially, circumferentially,

Digitized by Google

and laterally. When this brush-holder was in use the surface of the carbon was always uniform, and the commutation remained always the same, even if the brush were removed and then replaced.

Experimental Results.—The commutation phenomena already theroretically considered were experimentally studied by means of the magnetic oscillations recorded in coil 5 P on the pole shoe. The oscillations recorded were due both to the movement of the teeth in the main magnetic field and to the commutation of the armature current; but, as will be seen from Fig. 8, the two kinds of oscillations were easily distinguished from each other. Thus A shows the tooth oscillations alone as recorded on open circuit, and B the oscillations recorded on full load. C and D are records obtained by running the machine as a generator with full-load resistance in circuit, but with only one commutator brush down, the circuit being completed through a slip-ring connected to a point in the armature. In these two latter records, when the tapping point was in the neighbourhood of the commutator brush, only the tooth oscillation was recorded, and as the tapping-point rotated the commutation oscillation appeared until when the point was opposite the commutator brush the oscillation reached its maximum value. Thus C shows the magnitude of the oscillation due to the negative brush, and D that due to the positive brush. The magnitude of the positive brush oscillation was very much smaller than that due to the negative brush, not due to any lack of symmetry of the magnetic system, but entirely to a difference in the natural period of the short-circuited coil when under the positive and when under the negative brush.

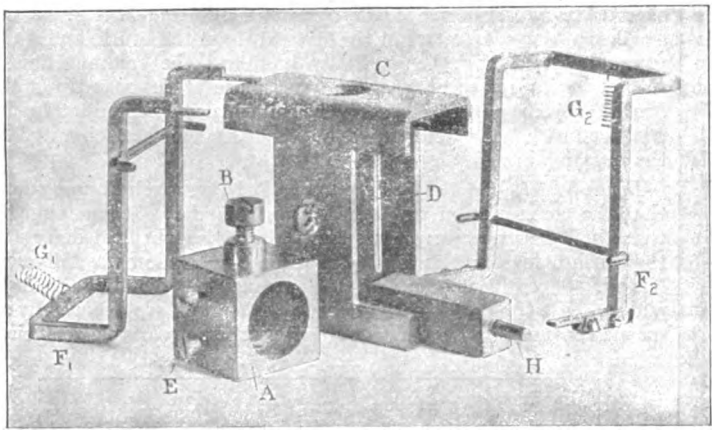

Fig. 7.—Parts of Brush-Holder.

Since the magnitude of the positive brush oscillation was less than that of the negative, the natural period of the former was less than

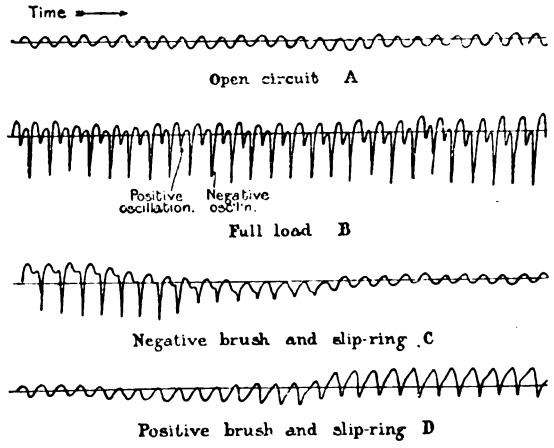

Fig. 8.

that of the latter, and since it may be assumed that the self-induction in the two cases is the same, it follows that the contact resistance of the brush when positive was higher than when negative. This result agrees with those obtained by Arnold and others.

The commutation oscillation consists of a single peak; the magnitude of the peak is proportional to the maximum rate of change of the current in the short-circuited coil and its magnitude and position in relation to the contact maker indicates the nature of commutation taking place. When the peak is small and occurs early, the commutation is efficient; but when the peak is large and occurs late in the period, the commutation is completed by a rush of current and sparking is liable to take place.

The resultant oscillation in a given machine may have eight different shapes. The shape is determined by three factors—*i.e.*, direction of rotation, direction of current and direction of field. Fig. 9 shows the various shapes of oscillations obtained, and the circles to the right of the figure show the relations of the three factors referred to. The curved arrow indicates the direction of rotation, the horizontal arrow that of the current and the vertical arrow that of the field. If the commutation oscillation peak occurred exactly at the middle of the period, record G would approximately correspond to A, record H to B, record E to C, and record F to D, and there would only be four varieties of resultant oscillation. The movement of the peaks to the left can be very clearly seen by comparing the records as above.

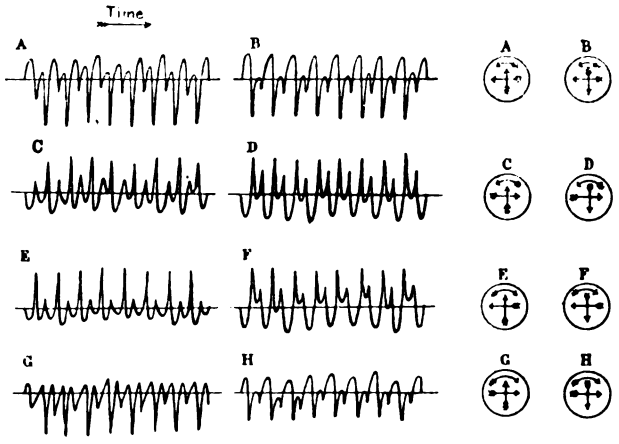

Fig. 9.

Still another variation can be given to the shape of the resultant oscillation by shifting the brushes through a fraction of a period, and thus displacing the phase of the commutation oscillation in relation to the tooth oscillation. The actual magnitude of the negative peaks when produced by the normally positive brush is not exactly the same as when produced by the normally negative brush, and vice versa. This is partly on account of their differing relation to the tooth oscillation, and partly on account of the fact that a brush normally positive required to run a very long time (usually several days continuous running) before it became a normal negative one.

Influence of Contact Resistance on Commutation.—A very marked influence on the commutation taking place was also noted when the commutator was respectively cold and hot. Fig. 10 shows the records obtained. A was recorded when the commutator was cold after standing over the week-end; temperature of room 15°C. B was recorded after the machine had been running several hours and the commutator had attained the temperature of 29°C. The negative oscillation increased considerably with rise of temperature, while the positive oscillation diminished slightly. This was caused by a decrease in the contact resistance of the negative brush, while that of the positive brush varied but little.

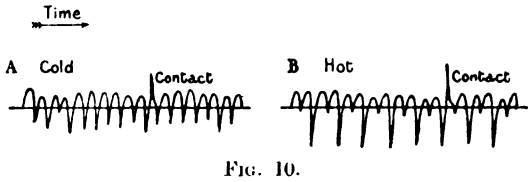

Fig. 10.

The author also illustrates the influence of contact resistance on commutation by records obtained under the same conditions, but when a little petroleum had been rubbed on the commutator. The petroleum increased the contact resistance and thereby reduced the natural period of the short-circuited coil with the resulting diminution of the oscillation and the maximum rate of change of the current. The least trace of petroleum is sufficient to influence commutation.

Disposition of the Contact Resistance.—It was pointed out in the theoretical discussion that commutation could sometimes be improved by a proper disposition of the contact resistance over the brush surface. This was effected by means of the brush shown in Fig. 5. Only the negative brush was varied, as the commutation under the positive brush was already very satisfactory. The negative oscillation was gradually reduced in magnitude as the width of the forward portion of the brush surface was reduced, until the width of the latter was a minimum consistent with mechanical strength.

Digitized by Google

In this shape of brush the contact surface of the brush is equally divided between the two segments when about one-quarter of the short-circuit period has expired, and just before one-half the period the contact resistance over the forward segment is confined to the narrow strip at the forward tip of the brush. The reduction of magnitude of the oscillation is, as pointed out in the theory, due to earlier commutation. With a full surface the negative brush had a tendency to spark on full load, but when the forward surface was reduced to 2½ mm. all sparking disappeared, and with a 2 mm. surface the machine could be run on a 75 per cent. overload without any trace of sparking. Thus the overload capacity of a machine may be greatly increased by a suitable disposition of the contact surface.

The same experiment was tried with the positive brush, but with very different results. The positive oscillation was very small even with the full surface, and hence any alteration in the brush surface could hardly improve matters. When the brush was cut away the oscillations immediately increased to about the same magnitude as those due to the negative with the full surface brush.

(To be concluded.)

EDISON STORAGE BATTERY.*

ITS PRE-EMINENT FITNESS FOR VEHICLE SERVICE.

BY W. E. HOLLAND.

Summary.—A detailed description is here given of the Edison cell and of the experiments which led up to its present form. In conclusion, the features of the cell are discussed.

The "A" type Edison cell is the outcome of nine years of costly experimentation and persistent toil on the part of its inventor and his associates. The principle on which the action of this new battery is based is the oxidation and reduction of metals in an electrolyte which does not combine with, and will not dissolve, either the metals or their oxide; and an electrolyte, furthermore, which, although decomposed by the action of the battery, is immediately re-formed in equal quantity, and, therefore, in effect is a constant element, not changing in density nor in conductivity. A battery embodying this basic principle will have features of great value where lightness and durability are desired. For instance, the electrolyte being a constant factor, as explained, is not required in any fixed and large amount, as is the case with sulphuric acid in the lead battery. Thus, the cell may be designed with minimum spacing of plates and with the greatest economy of space that is consistent with safe insulation and good mechanical design. Again, the active materials of the electrodes being insoluble in, and absolutely unaffected by, the electrolyte, are not liable to any sort of chemical deterioration by action of the electrolyte, no matter how long continued.

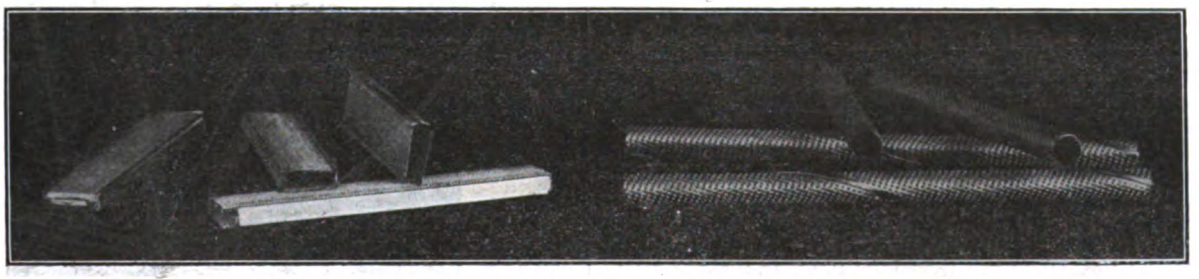
Those who have had experience with lead batteries know what attentive care is required to prevent "sulphation," which is caused by chemical action of the electrolyte on the active materials. They will also appreciate that such a disease-free battery as this is the augury of a beneficient revolution in electric vehicle practice.

The electrolyte of the Edison battery is a 24 per cent. solution of potassium hydrate, having in addition a small amount of lithium hydrate. The active metals of the electrodes—which will oxidise and reduce in this electrolyte without dissolution or chemical deterioration—are nickel and iron. These native elements are not put in the plates as metals, but one (nickel) in the form of a hydrate, and the other (iron) as an oxide. The containing cases of both kinds of active material (Fig. 1) and their supporting grids (Fig. 2), as well as the cell poles with connection parts (Fig. 3), and even the retaining can and its cover (Fig. 4), are all made of nickel-plated steel, a material in which lightness, durability and mechanical strength are most happily combined, and a material beyond suspicion as to corrosion in an alkaline electrolyte.

An essential part of Edison's discovery of active materials for an alkaline storage battery was the preparation of these materials. Metallic powder of iron and nickel, or even oxides of these metals, prepared in the ordinary way are not chemically active in a sufficient degree to work in a battery. It is only when specially prepared iron oxide of exceeding fineness and nickel hydrate conforming to certain physical as well as chemical standards can be made that the alkaline battery is practicable.

Having discovered the basic elements of the alkaline storage battery, the inventor set about to find the best means of supporting and making electrical connection with the active materials and to perfect the mechanical design. It was found, as expected, that the active materials were not of themselves sufficiently conductive to work efficiently except in exceedingly thin layers. Some conducting substance which would not be changed by chemical action must, therefore, be mixed with the active materials to bring every particle into good electrical contact with the conducting support. Graphite was first thought of and was tried, both with the iron and with the nickel material. At first it gave only fair results, but after a particular quality in the form of thin scales had been developed the results were good. It was soon superseded in the iron electrode, however, by mercury, which was found to hold the iron particles in much better contact and give better voltage to the cell at high discharge rates.

In the nickel electrode graphite was used until the recent advent of the "A" type cell. The results as to capacity were good when cells were new, showing that graphite performed well the function of bringing every particle of the active nickel into good electrical contact with the conducting support. But, unfortunately, in time it became apparent that this most durable form of conducting carbon was unable to withstand the disintegrating action of the strong oxidisers formed at the nickel electrode during charge. The result was that cells of this type, in service, would gradually lose capacity from deterioration of internal contacts in the nickel plates.



Fe. Ni.

FIG. 1.—THE TWO KINDS OF PERFORATED CONTAINERS INTO WHICH THE IRON AND NICKEL ACTIVE MATERIALS ARE LOADED.

One other feature of the former types of this cell remains to be commented on as a point contributory to their deterioration. It is a bothersome characteristic of all storage batteries that the active materials expand and contract during charge and discharge of the cell. This point was not properly taken care of in the first types produced, although much attention had been given to it. In the "E" type, the immediate predecessor of the "A" type, rectangular containers (like those used in the iron plate to-day) were used for supporting both kinds of active material. These containers, after loading and mounting in a support grid, were subjected to heavy pressure in a die designed to concave and corrugate each loaded container, or pocket, the idea being to make an elastic construction which would maintain a constant spring pressure on the active materials. In the iron plate this construction proved perfectly satisfactory, and, as mentioned, is still used.

The nickel material proved more troublesome, however. It would expand when charged, and would not contract again; and its expansion was found to be cumulative, increasing gradually in extent, until in time the elastic limit of the perforated steel was exceeded, and the internal contacts became disarranged. Notwithstanding these facts, the "E" type Edison cell, with nickel plates of flat-pocket construction and containing graphite, was used in commercial service with excellent results, having a useful life of from three to five years, and showing itself to be more economical than the lead battery and much more dependable.

In the "A" type cell the construction of the two kinds of plate is radically different. The negative, or iron plate (Fig. 5), has the familiar flat-pocket construction. Each negative contains 24 pockets, a pocket being ½ in. wide by 3 in. long, and having a maximum thick-

* Abstract of an article in the "Electrical World,"

Digitized by Google

ness of a little more than $\frac{1}{8}$ in. The positive or nickel plate (Fig. 6) is seen to consist of two rows of round dots or pencils, 30 in number, held in a vertical position by a steel support frame. The pencils have flat flanges at the ends (formed by closing in the metal case), by which they are supported, and electrical connection is made. The frame is slit at the inner horizontal edges, and then folded in such a way as to make individual clamping jaws for each end flange. The clamping is done at great pressure, and the resultant plate has great rigidity and strength. The perforated tubes into which the nickel active material is loaded are made of nickel-plated steel of high quality. They are put together with a double-lapped spiral seam, to give expansion resisting qualities, and, as an additional precaution,

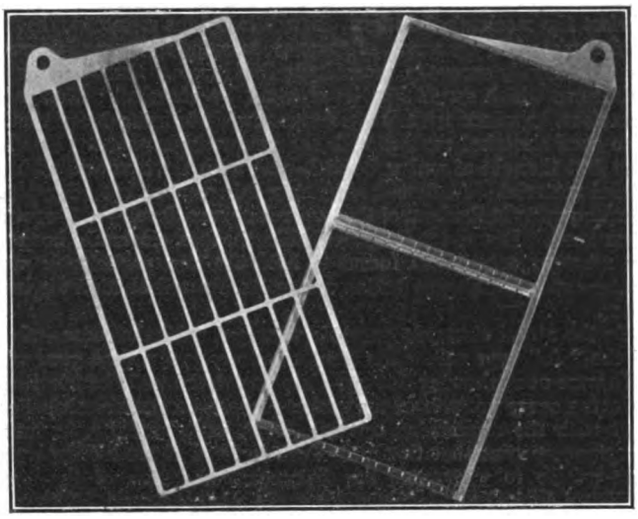


FIG. 2.—THE TWO TYPES OF SUPPORTING GRIDS.

small metal rings are slipped on the outside. Each tube is $\frac{3}{4}$ in. diameter by $4\frac{1}{8}$ in. long, and has eight reinforcing rings.

It will be seen that the "A" positive plate has been given the theoretically best design, to prevent expansion and overcome trouble from that cause. Actual tests, long continued under very severe conditions, have shown that the construction is right and fulfils the most sanguine expectations.

The use of graphite was not so easy to eliminate. The inventor realised that a metal insoluble in the electrolyte and able to withstand electrolytic oxidation was the logical thing, and, naturally, he thought of nickel at once; so nickel and other metals were tried in various forms and under different conditions of mixture with the nickel hydrate. The results at first obtained might have been considered good had the inventor not previously developed the efficiency

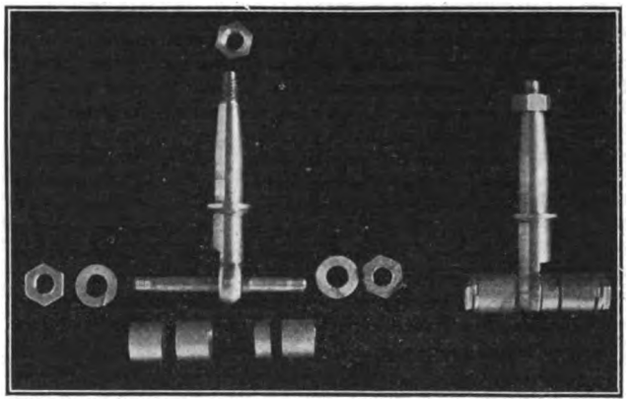

FIG. 3.—CELL POLES AND THEIR CONNECTIONS.

of graphite so far, and known what high specific capacity could be realised in nickel hydrate. As it was, the results were considered unsuccessful. Eventually nickel was found to give highly satisfactory results if made into thin flakes of a certain quality and loaded into the tubes in layers interspersing with layers of nickel hydrate.

An idea of the conditions inside a loaded tube can best be had by microscopic examination. Fig. 7 shows a magnified section of a regularly loaded tube which has been sawn lengthwise. The vertical bounding walls are edges of the perforated metal containing tube; the dark horizontal lines are layers of nickel flake, while the light-coloured thicker layers represent the nickel hydrate flake. It should be noted that the layers of flake nickel extend, practically unbroken, across the tube, and make contact with the metal wall on both sides. These metal layers conduct current to or from the active nickel hydrate in all parts of the tube very efficiently. There are about 350 layers of each kind of material in a $4\frac{1}{8}$ in. tube, each layer of nickel hydrate being about 0·01 in. thick; so it will be seen that the current does not have to penetrate very far into the nickel hydrate, one-half a layer's thickness being the maximum distance. The perforations of the containing tube, through which the electrolyte reaches the active material, are also shown in Fig. 7.

From the foregoing it will be understood that the troublesome member of the Edison battery has always been of nickel. The iron active material and the design of the iron electrode were developed to a high degree of perfection some years ago, and have since remained unchanged, except that improvements have been made in the manufacturing processes.

The characteristics of the Edison battery, which fit it so pre-eminently for transportation service, may be summarised as follows: (1) The perforated container construction prevents loss of material by disintegration, doing away with sediment short-circuits and the necessity of cell washing. (2) A steel containing can has very obvious mechanical advantages over a hard rubber jar, and the expensive delays and trouble caused by jar breakage in lead batteries

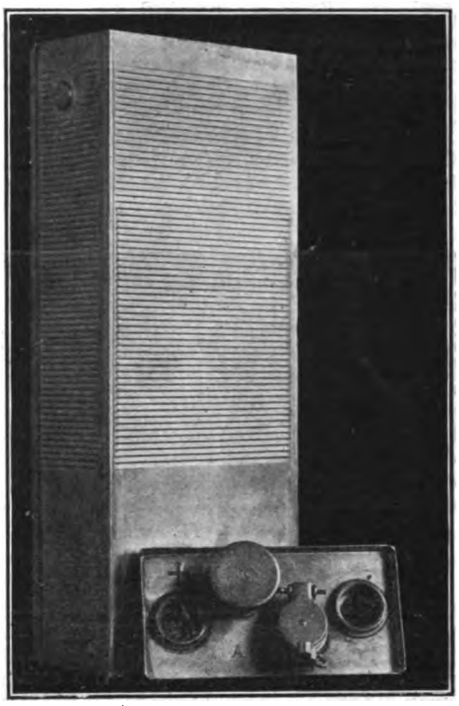

FIG. 4.—THE RETAINING CAN AND ITS COVER.

is thus eliminated. (3) The steel and copper connectors used in connecting cell posts are easily removable, and make it possible to disconnect or replace any cell of a battery in a very short time without the employment of skilled labour, such as a "lead burner." (4) The steel and nickel construction of the plates makes "buckling" impossible; even a dead short-circuit of the poles will not affect the condition of the plates in the slightest. (5) The simplicity of the care required enables one garage man to look after a large number of batteries, or makes it possible in private service for anyone to care for and operate his own pleasure vehicle with little trouble and most satisfactory results. (6) The materials used in the cell being exceedingly durable by nature, and the construction being very rugged, a cell will stand an almost unlimited amount of vibration and shock without injury. (7) Freedom from "sulphation" or any kind of chemical corrosion eliminates a very insidious source of trouble and depreciation. (8) Lack of corrosive fumes prevents destruction of the metal work of vehicles and of the garage equipment. (9) The light weight of the battery in comparison with lead batteries gives it many evident advantages. The wear on tyres is reduced; the vehicle can be built lighter; the cost of battery and of charging current required for moving unprofitable load—*i.e.*, the weight of battery and vehicle—is much reduced, or, in other words, a much larger percentage of the total weight transported will be paying load. This characteristic of lightness also makes possible the building of

Digitized by Google

machines of exceedingly high mileage capacity. (10) The crowning feature of the Edison battery, however, is its great durability. It is safe to say that this feature alone would have insured the battery's success without the many attendant advantages which it possesses. (11) The so-called efficiency of the Edison battery is low, being normally about 60 per cent., where a lead battery, if new and in good condition, would give 75 to 80 per cent. If charging current were the principal item of expense in vehicle operation this fact might be serious, but it is universally recognised that cost of charging current is an insignificant item, and of no practical account in comparison

FIG. 5.—THE NEGATIVE OR IRON PLATE.

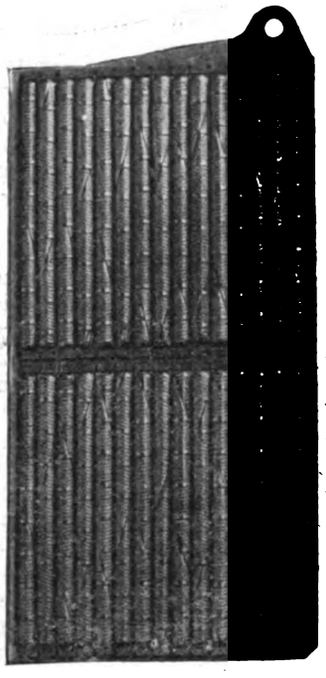

FIG. 6.—THE POSITIVE OR NICKEL PLATE.

with the other factors of care and maintenance. Moreover, as is well known, a lead battery does not long remain "new and in good condition," and its high first efficiency accordingly is not maintained. The true measure of a battery's efficiency is the ratio of the total cost of operation over a long period of time to the load carried and the distance travelled, due allowance being made for reliability. Expressed in a formula

$$\text{Practical efficiency} = \frac{\text{Total cost of maintenance and operation}}{\text{Paying load} \times \text{miles carried} \times \text{reliability factor}}$$

the "reliability factor" being percentage of working time that the

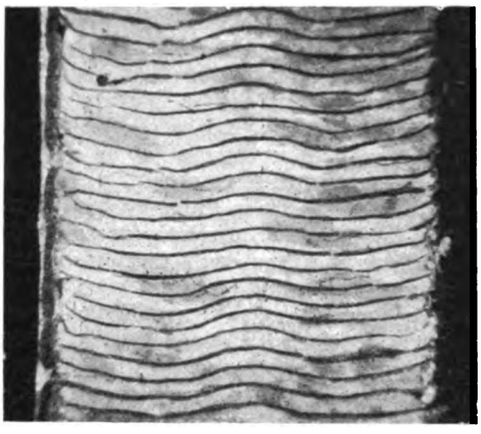

FIG. 7.—SECTIONAL VIEW OF A LOADED TUBE, MAGNIFIED ABOUT 8 DIAMETERS.

machine is in commission. In the light of this practical formula it can truly be said that the efficiency of the Edison battery is high—much higher than that of any other.

In conclusion the writer says that the points here presented are not speculations or mere assertions, but are proven facts, the results of innumerable laboratory and road tests which have come under his direction or observation.

THE APPLICATIONS OF ELECTRICITY AT THE PANAMA CANAL.

The Panama Canal is very much in the public eye at the present time, chiefly, it must be admitted, owing to the extra enormous expense which it is now anticipated will have to be met before this work is completed. It is impossible to estimate the cost of so stupendous an undertaking with any degree of accuracy until the construction is fairly well advanced, and rarely has this fact been so well instanced as in this case, where the ultimate outlay necessitated will be about three times that which was originally expected. It is natural, therefore, that every economy which it is possible to effect is now being brought forward, and hence the adoption of electricity, with its efficiency in operation, has been on a larger scale than is usual with this class of work.

The arrangement of the Canal in outline is, first, to remain at sea level from the Atlantic Ocean entrance to the Gatun Locks, which are in three flights, the distance being about 5 miles. Here the water level will be raised 85 ft., and continue thus till the Pedro Miguel Lock, which will be at the entrance to the Miraflores Lake, some 5 miles from the Pacific coast. At this point the level will drop to 50 ft. above sea level, sea level being reached through the Miraflores Locks (a flight of two), which will be situated at the other end of the Miraflores Lake.

While the general work of excavation will be on a huge scale throughout the whole length of the Canal, it is easy to see that the most important portion of it is concentrated at the three sets of locks, and it is not surprising, therefore, to learn that the electric generating stations are situated in the vicinity of the locks. At Gatun, where the largest and most difficult work has to be accomplished, owing to the provision of three flights of locks, a large power house is already in operation, and while it has been erected entirely for the constructional needs of the Canal, it will serve permanently for the production of power required for various purposes when the Canal is in operation. The installation consists of three 1,500 kw. steam turbo-alternators, alternating current being used almost exclusively for all purposes. The alternators are three phase, and generate current at 2,200 volts, with a frequency of 25 cycles per second. There are three rotary converters in the power house, one of 300 kw. and two of 500 kw. each, for supplying direct current, which is employed for certain special purposes. The design of the power house is in accordance with modern practice, and separate pairs of boilers are installed for each turbine set. From the Gatun generating station power is taken to various parts of the Canal in the vicinity, cables being, in the main, carried on poles. A second power station at Miraflores is now nearly completed, and will be exactly similar to the existing one, and contain an equal amount of plant, and supply power for all the work at Miraflores and Don Miguel Locks. The two stations will work in parallel after the Canal is completed, or may be arranged to supply separate portions of the Canal and be independent. An interesting feature of the new power house lies in the fact that it is built in reinforced concrete.

Apart from these two main power stations, there are three smaller and older ones, which are now worked by the Canal authorities, though previously under the control of the Panama Railroad Co., and they are chiefly for the purpose of supplying current for lighting and various power purposes in the towns where they are situated. They are all on the Pacific side of the Canal, one being at Balboa, on the coast, one at Empire and one at Gorgona, which is practically midway between the Atlantic and the Pacific. At these places there are large labour encampments, and the demand for lighting is continually increasing, some 20,000 lamps being installed in various districts during last year. In spite of the stations being small and not modern, and the load chiefly a lighting one, the total cost of production is only about 1½d. per unit, with a total output for the three stations of about 4,000,000 units annually.

Returning to the large power station at Gatun, the chief demand for power is in the handling plant, which has been installed for the construction of the locks and dams. Sand and cement are brought up to a barge dock through a channel from the French Canal, and are there unloaded, the cement being transferred direct to the cement shed alongside by means of 10 electric cranes, while the sand and stone are conveyed to a large heap some 500 ft. nearer the lock by means of one single and one duplex Lidgerwood cableway, the towers for which are some 800 ft. apart, and run on rails, so as to be moved to any position as required. There is an automatic electric railway, which conveys cement, sand and stone to the electrically operated mixers, which are situated close to the middle of the centre of the three locks, and the mixed concrete is loaded on another automatic electric railway running parallel to the three locks for their whole length. From this railroad the concrete is transported as required

Digitized by Google

to build up the locks by means of four duplex Lidgerwood cableways, which span the locks and have towers some 75 ft. high and about 800 ft. apart. These run on tracks parallel to the axes of the locks, and can readily be travelled to suit the work.

All these Lidgerwood cableways are electrically operated, and are quite self-contained, and the adoption of electricity is somewhat of a novelty, since it is not often that, in works of this nature, electric power is available. One motor is sufficient for all the movements, and by means of friction drums the bucket can be hoisted, run out, tipped and returned; but it has been found that the employment of two motors with a series-parallel control, as with a tramway system, is much more economical and convenient. In raising the bucket the motors are put in series at first, and the hoist is accomplished at a moderate speed; but in traversing the buckets the motors are in parallel, and a very much more rapid motion of the bucket is obtained than would be the case if the speed were limited to that allowable in lifting the load. It is evident that, for this purpose, electricity has a great advantage over steam for operating cableways, and it has been found that the economy in the working of this plant has been very marked.

There is a large amount of pumping machinery electrically driven at various parts of the Canal, and at the Gatun Waterworks a turbine pump capable of dealing with 70,000 gallons of water per hour has recently been installed, indicating how rapidly the demand for water is increasing. In view of this, it has been decided to construct an entirely new pumping station, together with a reservoir of a capacity of 600 million gallons of water. All the pumping plant will be electrically driven, the type employed being the efficient and comparatively cheap high-pressure turbine pumps, which are now so effectively ousting the duplex and triplex machines.

Electricity is always an important factor in the difficult and dangerous operation of rock blasting, and the common method employed is to fire the fuses in series by means of magneto ignition. At Panama this led to many accidents, and did not work at all satisfactorily, the fuses frequently failing to fire, and being a considerable source of danger to steam shovels if left. The means now adopted is to have wires running the greater length of the Canal, current being supplied from one of the lighting stations at 2,300 volts. From these cables wires are taken to small 5 kw. transformers, with a ratio of 20, and from the secondary current is taken (at about 110 volts) to a number of fuses, usually about 100 at a time, connected in parallel. It has been found that misfires are practically unknown, and there is the further advantage that, as so large a number of fuses are exploded at once, a relatively greater amount of rock is dislodged than by the previous arrangement. The holes are drilled some 5 ft. or 6 ft. into the ground and are 3 in. or 4 in. in diameter.

When the Canal is completed there will be a large demand for power from various users, and this demand will rapidly load up the plant rendered available for other purposes by the completion of the constructional work. It is probable that various works will be opened up, besides which there will undoubtedly be electrically-operated light railways and tramways, and one of the most interesting applications of electric power will be its employment for towing vessels, since these will not be permitted to enter the locks under their own steam. The probable method adopted will be to have powerful electric locomotives running along the sides of the locks, while electric capstans will, of course, be employed. There will be numerous electric cranes, and it is proposed to work the many gates and valves by electricity, and the 9,000 kw. provided at the two large power stations mentioned above will be none too much for the entire electrical equipment of the Canal when it is in full swing.

ELECTRIC CABLES.*

ELECTROLYSIS.

BY F. FERNIE.

Summary.—The author first considers the general phenomena of electrolysis as observed in the neighbourhood of electrical networks. He then discusses in more detail the corrosion of lead-covered cables and armoured cables, and the effectiveness of earthing.

Probably no general rule can be laid down for the protection of underground cables and pipes from electrolysis. The conditions on every system vary, and each case has to be considered separately. The conduction of soil is probably entirely electrolytic; hence the nature of the soil—the kind of salts which it contains—largely influence the amount of electrolysis. Corrosion chiefly occurs on those cable sheaths or pipes which are at a higher potential than the surrounding soil, and become the anode of the electrolytic cell thus formed. The corrosion of a metal anode is caused by the combination of the metal with a variety of anions, which may be oxygen, OH, NO_3, SO_4, CL, and other acid radicles. Corrosion of lead generally results in the formation of various oxides, which, being insoluble, will be found at the point of corrosion. Nitrates and nitrites cause a large electrolytic corrosion of lead, but lead nitrate is readily soluble in water, and may, to a large extent, disappear. Lead oxides formed will slowly turn to carbonates by absorption of Co_2. Chalk and other carbonates tend to decrease the corrosion of lead. The corrosion of iron also produces the formation of iron oxides. Chlorides tend to increase the action and nitrates to diminish it.

The corrosion of iron depends on whether the surface is active or passive. Iron in the passive state is assumed to be covered with a thin film of oxide ($Fe_3 O_4$) or oxygen, which acts as a kind of varnish and protects it from further corrosion. Iron can be made passive by treatment with nitric acid, so that on re-immersion in the acid it is not attacked, if the surface be not rubbed. Iron is also rendered passive by immersion in molten caustic potash or soda (free from water), and to some extent by alkaline solutions. The presence of carbon dioxide, however, may cause passive iron to corrode. Carbon dioxide is supposed to play an essential part in the ordinary rusting of iron. In Edison's iron-nickel accumulator, the iron is prepared in a special way in order to make it active. Iron can be changed from the active to the passive state by a high current density. Possibly the mechanism of the passive condition of iron may be similar to the "valve action" of aluminium and other metals with alternating currents. Galvanised-iron pipes afford an instance of kathodic (secondary) corrosion. Electrolysis of the soil causes an alkaline liquid to collect at the cathode, resulting in the removal of all the zinc and followed by very rapid "chemical" corrosion of the iron.

Intermittent currents may also corrode an iron cathode, by causing alternate oxidation and reduction. (By "intermittent" currents are meant continuous currents, with occasional stoppages of perhaps some hours.) Alternating currents may cause serious corrosion under certain conditions, more particularly of lead. The amount of corrosion depends on a large number of conditions, amongst which are frequency of the current, the nature of the electrolyte, and current density. It would seem that when any irreversible chemical change takes place at an electrode, alternating currents must cause corrosion. For instance, if, when a metal electrode is anode, it forms metal cations; these may combine with some of the anions to form an insoluble salt, so that the metal ions cannot be re-deposited at the succeeding half waves; or a soluble salt may be formed in the first instance, which a secondary action may convert into an insoluble salt. For instance, lead plates in a solution of sodium nitrate and sodium carbonate might be converted into lead carbonate by an alternating current, the soluble lead nitrate first formed being converted by a secondary action into the insoluble lead carbonate. It is obvious that the frequency of the current must considerably affect such actions. The rate of diffusion of ions in the electrolyte must also have some influence on the rate of corrosion, for a certain proportion of ions formed may diffuse away from the electrode, thus escaping re-deposition, and causing slow corrosion. The lower the frequency the more this would tend to occur. Also other ions in the solution may be more readily discharged than the metal ions formed from the electrode, thus allowing a number of the metal ions to diffuse away. The corrosion caused by alternating currents is generally less than 1 per cent. of that due to an equivalent continuous current, but under suitable conditions, the corrosion (of lead in particular) may be much greater than this. In general, increasing frequency decreases the corrosion. Iron, however, in some solutions is said to corrode more rapidly as the frequency is increased, probably up to some limiting value.

It is a difficult matter to differentiate electrolytic and chemical corrosion. Electrolytic corrosion generally causes rough irregular patches on the surface of the lead, whilst

regular cone shaped holes are sometimes eaten into the lead by chemical corrosion. Similar shaped holes are occasionally caused by electrolysis, where the lead is only touching the electrolyte at points, the holes being filled with oxides of lead. Even where comparatively large patches of lead are affected by chemical corrosion, the outline of the patch and the depth are generally regular. Holes are sometimes burnt in lead by arcs, and the holes resemble the cone-shaped holes mentioned above. Electrolytic and chemical corrosion being probably one and the same thing ultimately, the mere appearance of the pitting is not sufficient to distinguish them.

Small pipes are subject to more rapid action than larger pipes, for with any given current strength the current density must be greater on their surfaces. Also with any given potential difference the apparent surface resistance of any given area of a small pipe is less than that of a corresponding area on a larger pipe, and hence the current density must be greater in the case of the smaller pipe. Cast iron is less readily corroded than wrought iron. A coating of rust on a pipe may help to protect it, but on the other hand, might increase the corrosion by exposing a larger area of metal, owing to the roughening of the surface beneath the oxide, and might also decrease the contact resistance by encouraging a more intimate contact of moisture with the metal.

Current leaves a pipe surface chiefly on the side nearest to the rails or other cathode, and the amount of current leaving the opposite side of the pipe, and "bending round," appears to be inappreciable, judging by the localisation of the corrosion.

A buried cast-iron pipe that has been subject to electrolysis—one that has formed an anode—is easily recognised. Its external appearance is not much altered, but if the electrolysis has been of long duration, the whole of the pipe will be found to have lost its crystalline structure and all metallic lustre. It will have somewhat of the appearance of a soft shale, and layers can be readily prised off with a knife. In bad cases, a penknife blade can easily be driven through the pipe. Pipes that have not been electrolysed very long have only the outer skin affected, and when this is flaked off, the metal underneath is found hard and normal. To give an instance, a central supply station (three-wire continuous current) had a more or less permanent leak on the negative main, and for two or three years the leakage current seldom shewed a less value than 10 amperes. Consequent upon this, a number of cast-iron water pipes close to the station were found when dug up to be in the condition described above, so much so that it was impossible to take some lengths out, without breaking them. A cast-iron pipe laid in a sandy soil, and containing a third wire cable, the insulation on which had broken down, was found to be in a very similar condition. This pipe probably acted as an anode whenever there was a leak on the negative side of the system. Owing to the insulating, quickly drying nature of the soil, the current density must have been very small. A third case may be mentioned of a cast-iron pipe laid parallel to a solid laid distributor. This cable was positive, and developed a fault which continued for some months, the total leakage current at any time being certainly less than one ampere. The pipe for some feet on either side of the fault was partly converted to this characteristic shaly state. The current appeared to have got on to the pipe immediately opposite the fault, and to have left it chiefly on the side opposite to that on which the cable lay.

On the other hand a chemically corroded iron pipe, such as one that has been laid in ashes, is entirely different in appearance. It is roughened and pitted, possibly with holes eaten in it in places, and often shows a variety of colours. Very old gas service pipes often have this appearance. Electrolytic corrosion also sometimes takes the form of pitting; the appearance of the corroded iron probably depends on the nature of the soil, and to some extent on the kind of iron.

The surface resistance between pipe and earth has been found to equal about 0·2 ohm per square metre, and the resistance of a metre cube of earth to be about 125 ohms.*

If the soil is very dry and of poor conductivity, then very little current will be shunted out of the rail, unless special facilities occur for it. For instance a water pipe laid parallel to the rails might be generally buried in a dry soil, but which contained here and there conducting patches of wet soil. Such patches might be caused by leaky joints in the pipe; in such a case most of the shunted current would flow in the pipe itself and corrode it where it left the pipe. Probably pipes which form a "short cut" for the return current are those most likely to carry large currents.

The potential difference measured between rails and pipes, &c., will in general be a resultant E.M.F., as there are, in addition to the E.M.F. caused by the current, back E.M.F.s caused by polarisation at the surfaces of pipes. Messrs. Cunliffe (*v.s.*) regard pipes laid at a greater distance than 3 ft. from the rails as out of danger, because nearly the whole fall of potential due to a current flowing in soil is within 3 ft. of the electrodes. If a pipe near the rails differs from the rails by a potential v, then all other pipes further from the rails than this pipe will, if there is no current flowing in them, be also at a potential v with regard to the rails. Similarly if the earth is regarded as a conductor, then if all the fall of potential occurs within 3 ft. of the rails, all earth beyond 3 ft. will be at the same potential, and thus any pipe buried 3 ft. from the rails will be at the same potential as the earth surrounding it, so that no current will enter or leave it from the earth. Yet the pressure between the pipe and rails might be considerable. One case of tramway current corrosion we have seen was on a water valve, about 4 ft. from the rails; the soil was generally sandy, but there was a small leakage of water from the valve. A maximum difference of potential of 3·2 volts was observed between the valve and the rails, but in general it was about 2 volts, the valve being positive. The maximum potential difference between pipes and rails observed at Strasburg was 2·8 volts, and the mean 2·2 volts, with the pipes + , the maximum pressure with the pipes negative was 11·5 volts and the mean 4·0 volts, and there was "marked corrosion on gas and water pipes made of iron in the danger area, and in unfavourable soil." *

The lead sheaths of tramway feeder cables are obviously liable to electrolytic action and even fusion. American practice is to insulate the lead as much as possible and divide it into sections, while leadless cables are largely used in England. An attempt to earth and bond the lead of positive feeders is not to be commended, as it encourages heavy rushes of current along the lead whenever there is a momentary short-circuit on the system. Instances have occurred of several feet of lead being burned off such feeders by a short-circuit. No electrolytic trouble appears to have been recorded with single-phase traction lines, although the fall in potential along steel rails must be much greater with alternating currents—certainly twice as great for moderate frequencies.

Electrolysis on three-wire lighting and power systems is of a rather different order from that occurring on traction systems. The most serious form of damage, which is often called electrolysis, but which is not, is the burning and fusion of lead sheathings and pipes.

On a well-laid and well-maintained system of mains, earth currents of any magnitude do not normally occur. But on any fair-sized network there must always be small leakage currents, chiefly from consumers' premises and over "ends." Any damage caused by these small currents may be made inappreciable by bonding and earthing the lead sheathing of the wires. Bonding ensures a much larger surface by which the current may enter or leave the lead, and thus greatly reduces the current-density.

Efficient earthing prevents current leaving the surface of the lead at all. These small leakages are nearly always from the negative side of the system, and hence all the anodic corrosion must take place on neighbouring and better earthed sheathings or pipes. But the lead of a negative leaky cable is itself frequently corroded; for instance, where passing through cement or plaster, and the corrosion must be cathodic in these cases. It is probably a combination of chemical and electrolytic cor-

rosion, the latter acting as a reducing agent. Lead that forms the cathode of an earth circuit generally has a distinctive blue appearance, which is probably due to the removal of the film of oxide which exposed lead surfaces acquire. Lead covered wiring of buildings should undoubtedly be all bonded and earthed, since the whole installation is protected by fuses. The case is rather different, however, for street mains, where the danger is not so much electrolytic corrosion as fusing and burning. The method on which the mains are laid decides the course to be adopted. The initial difficulty is *efficient* earthing. The contact resistance of any earth plate which is carrying a current, and is an anode, rapidly rises, because it drives moisture away from it.

Whilst earth plates may lessen corrosion caused by minute currents, they cannot deal effectively with large currents. This is exemplified in the case of a fault occurring on a cable drawn into a galvanised iron pipe 50 ft. long and 2 in. external diameter, which caused the copper of the cable to be welded hard on to the pipe. About 18 in. away and running parallel was a lead water pipe. The P.D. between this and the galvanised-iron pipe was measured, and was 218 volts, yet the current passing was only 3 amperes! The soil was ordinary red garden loam. Permission may sometimes be obtained to bond the lead sheathings on to water pipes; this, of course, makes a capital earth, yet its expediency may be doubted. For suppose a network of lead-covered cables laid "solid," the lead being bonded together wherever possible and earthed at some point or points, the third wire being earthed at the station to a water pipe. On a fault occurring, the lead being in direct contact with the copper a very large current will flow, which is likely to burn off bonds here and there, but presuming everything holds up, it may shut down the station, or at any rate one section of the network, and reliability of supply becomes of greater importance every year.

A very good earth also defeats its object in another way, by forcing such a heavy current to flow along the lead sheath, between the fault and the earthing point, as to cause a considerable fall of potential along the lead. This tends to make the current arc to earth at intermediate points. This large current may be prevented by disconnecting the third wire earth connection, or by inserting resistance in it. If this be done the immediate effect is to raise or lower the third wire earth potential above or below earth some 200 volts or so. The result of doing this will be to start a number of third wire earths on any old network, chiefly on consumers' premises, and also nearly to double the potential between the opposite pole and earth. This will tend to cause additional faults, is contrary to the B.O.T. regulations, and may be dangerous to life. If a "solid" system is *perfect—i.e.*, with the lead everywhere insulated, there is obviously no object in earthing or bonding, for, supposing a fault to occur, there is no path for the current, and no current can flow. But there are, with most methods of laying, weak places, generally at saddles and where the cables enter manholes, where the current will get to earth and burn holes in the lead if there is no metallic path provided. Bitumen also breaks down and allows current to flow, if the lead be "alive" for any length of time.

These weak places may be far distant from the actual fault, and this is the danger of continuous lead without earth connections. Sometimes every saddle provides a path for the current, and corrosion then takes place at every such point. If now the lead be broken at short intervals, say at every joint, the corrosion or burning is limited to the particular length of cable in which the fault occurs.

This incidentally illustrates one of the advantages of a draw-in system, as with it the faulty length of cable is readily pulled out, examined and renewed if necessary. Further, long lengths of lead cables, all with the lead electrically continuous and earthed, actually invite tramway currents to travel along them. If the lead is insulated and broken into sections, there is no temptation to such currents to use it. On the whole, then, in laying down a system of mains, with the view of preventing electrolysis and burning, the surest method would appear to be to break the lead into sections, and thoroughly to insulate it. An attempt to do this is made on some British systems, but the more popular course is to bond and earth the lead; the earthing is done at definite places, an attempt being made to insulate the lead by laying the cable "solid" everywhere except at these points. The system devised by the Howard Asphalt Troughing Co., of insulating the lead and earthing sections through a light fuse, seems quite sound. The fuse acts as an indicator of the state of the section. It will, however, be often impossible to insulate the lead of service cables right up to the cut outs; but the service lead may be insulated from the main lead. A partial course is the worst, such as some cables bonded and some not, and partial or bad earths, such as earth plates generally provide.

The lead of lead-covered cables laid in metal pipes should be made as continuous as possible, and should be well earthed. An analogous case is that of two or more lead-covered cables in one duct, a fault occurring on one is sure to burn holes in the others if the lead of each cable is not thoroughly bonded to the rest. If it were possible to make a line of iron pipes electrically continuous by bonding at the joints or otherwise, they would thoroughly protect lead-covered cables drawn into them from electrolysis by tramway return currents.

(To be continued.)

THE GIROD FURNACE.*

BY W. BORCHERS.

Summary.—The author first describes the Girod furnace and gives details of its working and cost. He then refers to the works of the Société Anonyme Electrométallurgique Procédés Paul Girod at Ugine, giving particulars of the installation.

About six years ago,† the author, reviewing the progress of electrode furnaces up to that date, stated that a furnace simpler than that of Héroult could not be found. He had now to correct that judgment, for, in his opinion, the Girod furnace was now the simplest and safest, as far as construction and running of electric electrode furnaces were concerned. In the author's laboratory a Girod furnace of 30 kw. to 36 kw. capacity is being used, while elsewhere, for steel smelting, it is being used in sizes of 300 kw. to 1,200 kw. It is a combination of a resistance and an arc-heating furnace. The metal to be smelted serves as one of the electrodes; it is covered by the refining slag as an electrolytic conductor, while a carbon block (or several carbon blocks), introduced from above through the cover of the furnace, forms the opposite electrode above the centre of the bath. The arcs play between the carbon blocks and the slag, and no doubt here the largest amount of heat is produced. A second heat-producing zone is the layer of slag through which the current passes to and from the metal. Last, but not least, the metal itself becomes an important source of heat on account of the effective manner in which the electric current is made to pass through the molten metallic body, and this is the most important feature of the Girod process. The contact pieces are of such cross section and length that every one of them will take up only a certain part of the whole current without being overheated, and therefore without excessively increasing its resistance. An additional regulation of the temperature and resistance of each contact piece is effected by cooling the ends of these bodies, which contain small chambers, by means of circulating water. These bodies, which are made of pure iron to avoid any deterioration of the furnace charge, are therefore not only the conductors between the furnace charge and the current generators, but serve also to ensure regular and uniform distribution of the current traversing the centrally hanging carbon rod or rods radially to and from the periphery of the bath. This is important not only for uniformly heating the bath, but also for keeping every part of the liquid metal in constant motion. In running a furnace with as high a current density as is found necessary to smelt iron and steel, it can easily be observed that the passage and the transformation of the electric current into heat is accompanied by violent mechanical motion of all particles of the liquid. This movement, however, accelerates the contact between the impurities of the iron and the refining slag floating on top of the bath. The Girod system of arranging the electrodes and contacts is a safeguard against any stagnation of parts of the liquid furnace charge, and for this reason the advan-

tages of the induction or transformer furnaces and of electrode furnaces are combined in the Girod furnace, while the imperfections of both forms have been overcome.

The peculiar arrangement of electrodes and contacts gives the Girod furnace a special advantage over other electrode furnaces when cold scrap is to be smelted. As soon as possible after charging the hearth of the furnace the upper electrode is lowered until it rests upon the heap of scrap, and the current is compelled to pass by means of numerous small arcs through the whole mass of scrap to the periphery of the heap on the hearth bottom. The heap breaks down simultaneously in all parts in a very short time, and there is no sticking of cold pieces to the bottom of the furnace, and no necessity for stirring up and loosening such lumps from the hearth and endangering the latter. The author illustrates a 2½ ton and a 12 ton furnace, giving details of the size of the various parts.

It will easily be understood, that if, during a smelting operation, pieces of the ends of the contact bodies melt and dissolve in the steel, no harm will be done to the latter, as the contacts consist of pure iron, and the quantity of iron, which in such a case combines with the liquid charge of the furnace, is proportionally so small that the qualities of the charge will not be influenced thereby to any perceptible degree.

The applicability of the Girod furnace is in no way restricted by the nature of the raw materials. It may be fed with cold scrap or with molten metal. When feeding cold scrap the whole charge is not put in at one time. After the larger part of the charge has been shovelled or otherwise thrown upon the hearth, the current is sent through the heap in the manner already described. The rest of the charge is put into the furnace, together with the first batch of the refining ingredients. Taking a 2 ton furnace as an example, the charge consists of 2,000 kg. to 2,500 kg. of iron scrap, and the first batch of flux usually consists of about 80 kg. of lime and 220 kg. to 250 kg. of iron oxide in the form of ore, which, with the iron oxide that covers the scrap, serves as an oxidising agent. The smelting of the iron charge and of the first batch of refining flux requires four and a half to five hours. On the slag becoming exhausted of iron oxide, and, therefore, of its oxidising power, samples of the bath are taken and tested to ascertain the degree of refining of the molten metal. According to the degree of purification, the furnace now receives (of course, after the first slag has been skimmed off) a second, and if necessary a third batch of lime-iron oxide. After the removal of the last slag the surface of the metal bath is thoroughly cleansed by throwing in about 30 kg. to 40 kg. of lime and skimming this off after a while. The further treatment of the iron bath depends upon the presence or absence of impurities which could not be removed by the lime-iron oxide refining and upon the quality of steel to be produced. According to these circumstances, deoxidising or otherwise refining agents are employed, such as ferro-manganо-silicon, ferro-aluminium-silicon, ferro-manganо-aluminium-silicon, and other alloys. For producing carbon steels, an addition of Swedish charcoal iron or of a kind of iron very rich in carbon, made in a separate electric furnace of the steelworks, can be made. The final step in the production of special steels is the addition, after these refining operations, of iron alloys with metals like nickel, tungsten, and chromium.

The author, in the present Paper, confines himself to describing the practical working of the furnace. The total duration of one smelting operation from the starting of the current to the casting of the finished product into ingots or moulds covers about eight hours, assuming that the raw material is not pure. Pure raw material, of course, will require less time and less power.

The smaller of the two types of furnaces used in steel works are run with alternating currents of about 300 kw. at about 60 to 65 volts. The larger furnaces require 1,000 kw. to 1,200 kw. at 70 to 75 volts. Taking into account a loss of 10 to 11 per cent. of the charge by oxidation and evaporation, the power required to make 1 ton of steel in a small furnace is 900 to 1,000 kw.-hours, and, in a large furnace, 800 to 900 kw.-hours. The consumption of carbon electrodes amounts to 12 kg. or 15 kg. per ton of steel, including the short pieces, which remain in the holders, when the latter have reached the lowest point at which they can withstand the radiating heat of the bath.

The lining of the furnaces, mostly consisting of calcined dolomite, will withstand at least 80 charges. Thereafter the side walls, into which cavities have been eaten by the slag around the level of the molten bath, will require repairing, and these repairs will subsequently need to be effected at shorter intervals. The bottom of the furnace will, however, stand 120 to 160 charges without repair. The thickness of the bottom will have by then been reduced by about 100 mm. Furnace linings will stand a considerably longer time if liquid charges are used. One furnace working in this manner was run for 200 charges without any repairs. The linings of the furnace covers require more frequent renewal. In the small furnaces they need repairs after 25 to 30 charges, and in the larger furnaces after 20 to 25 charges. The other parts of the furnace are not worn out as fast as the linings and electrodes. The furnaces which have so far been put into operation still possess their original outfit.

At the works at Ugine only scrap iron is used as raw material for steel making as well as for the manufacture of iron alloys. The larger part of the scrap is soft iron and steel, the smaller part pig and cast iron. The average percentage of impurities in the raw material used over a long period of operations was:—Carbon 0·4-0·5 per cent., silicon 0·15-0·25 per cent., manganese 0·5 -0·7 per cent., sulphur 0·06-0·09 per cent., phosphorus 0·08-0·1 per cent. The degree of refining that can be reached in the Girod furnace can be seen from a table in the Paper, giving analyses of the various brands of steel produced.

The cost of the different types of Girod furnaces and of complete plants are as follows:—A small 2½ ton furnace, including regulators for the electrodes, measuring instruments, tilting device mechanism, and the conductors from the furnace to a dynamo or transformer near the furnace room, costs about £600. A large 12½ ton furnace with a similar outfit will cost about £1,200. The manufacturing costs of the electrodes amount to three or four francs per ton of carbon body. A complete plant with one 2½ ton furnace for regular running and one furnace for reserve, and with all appliances and melting house, but without dynamo or transformer, will cost approximately £8,000 to £12,000; and a plant working with a large 12½ ton furnace, £12,000 to £16,000.

To carry out the Girod processes for the purpose of making alloys and steel, a company, under the name of Société Anonyme Electro-métallurgique Procédés Paul Girod, Ugine, Savoy, in France, was formed several years ago. This Company is owner of the Girod Alloy Works, in which also the first experimental 2 ton steel furnace was tried. The fact that at the present day 19 furnaces with 400 to 600 E.H.P. are kept running, and that 12 new furnaces, each of 1,200 E.H.P., are being put up, shows to what extent this manufacture has been developed. In the future the older works will only make alloys, and the old steel furnace will be transferred to the new steelworks.

The Company also owns an electrode factory with the most perfect and modern installation, capable of turning out daily 10 to 12 tons of electrode carbons in diameters up to 350 mm. and in lengths up to 1,600 mm. of round or square cross sections. At present only 7 tons are made daily, for which only one furnace is required; a second furnace will be built as soon as the demand increases. The raw materials for the electrodes are retort graphite, petroleum coke, anthracite coal, and anhydrous tar. The solid materials are ground in ball mills, kneaded with tar in double screw mixers and in Chilian mills. The mixture is then stamped to big blocks which are finally pressed into blocks of the dimensions given above. The burning of these blocks is effected in gas-fired ring furnaces, the blocks being placed in large fireclay tubes and covered with coal dust.

The Company owns several water powers. The power house which was built for the old works is situated about 3 km. above Ugine, on the Arly river. Here a strong dam with gates diverts the water into a tunnel, which leads it to a pipe line directly above the power house at Ugine. Ten Pelton wheel turbines drive as many direct-coupled dynamos furnishing 8,000 to 9,000 E.H.P. The second power station, furnishing a further 12,000 E.H.P., is situated above Le Fayet. The tunnel and the pipe lines are large enough for carrying the water for 20,000 H.P., but the turbine house is only fitted with turbines and dynamos for the lower power. It will soon be enlarged. Three-phase current is transmitted at a pressure of 45,000 volts to Ugine, where it is transformed down to 2,500 volts for the large machines, and to 60 to 75 volts for the furnaces. A further reduction of pressure to 500 volts and to 110 volts is made, the last mentioned pressure being employed for lighting and for small motors, and 500 volt direct current for locomotives, cranes, &c.

Besides this power the works of Ugine are obtaining on lease 6,000 E.H.P. from a power station at Bionnay, upon the Bonnant river near St. Gervais, and during the winter months they also obtain 8,000 to 10,000 E.H.P. from the Société d'Electro-métallurgie Sud-Est at Veuthon, near Albertville. From both stations the current is furnished at a pressure of 45,000 volts.

The plant which has been installed for the new steelworks, most of which is now in running order, is as follows:—Three electric furnaces, each of 2 tons capacity. One of these only makes small steel castings. Two large electric furnaces, each of 10 to 12 tons capacity. The steel produced in all these furnaces, except the one mentioned, is cast into large ladles worked by electric cranes, and

Digitized by Google

run into ingots, which are sent to the rolling mills. Working with several furnaces steel castings (dynamo frames) up to 20 tons have been made. For the mechanical and thermal treatment of the steel ingots the most effective modern machinery and other installations have been erected.

The rolling mill has two three-high stands of rolls, one of which is able to take ingots up to 525 mm. diameter and 400 kg. weight, and rolls them down to rounds of 125 mm. diameter, while the other stand will roll ingots of 325 mm. diameter to smaller rounds, squares, and sections. The other outfit of this mill consists of two furnaces for heating the ingots before they go to the rollers, and of the necessary cutting and sawing machinery for the rolled blocks.
